First Version: December 2014; This Version: January 2016

#### Abstract

We investigate the impact of product market advertising on investor attention and financial markets. Using daily advertising data we can identify short-term effects of advertising. We develop a new proxy for investor attention based on a company's Wikipedia page views and show that advertising has a positive impact on investor attention, but only very little impact on turnover and liquidity. Most importantly, asset prices are not influenced by advertising in the short run. These findings are different from studies using yearly advertising expenditures and suggest that attempts to temporarily inflate stock returns via short-term adjustments to advertising are ineffective.

Keywords: Advertising, Investor Attention, Wikipedia, Turnover, Liquidity, Returns

### 1 Introduction

In this paper, we examine whether firms can create investor attention through marketing and challenge the widely held view that firms can influence short-term stock prices via product market advertising. Existing studies agree that product market advertising is positively linked to contemporaneous returns on stock markets (e.g., Chemmanur and Yan (2011) and Lou (2014)). The idea is that advertising leads to increased attention among potential investors, which then increases stock prices. (Barber and Odean (2008) or Merton (1987)). Understanding the impact of marketing on capital markets is important, as it might give rise to incentives for managers to use advertising in an opportunistic way to influence stock prices around corporate events.

However, existing studies on advertising and capital markets typically rely on annual balancesheet data on advertising. Thus, it is difficult for them to establish a causal link from advertising to capital market outcomes. In contrast to the earlier literature, we use a unique dataset containing high frequency advertising expenditures on the daily level to examine the impact of product market advertising on investor attention and eventually financial market outcomes. As advertising is typically pre-determined over longer horizons than a couple of days, our high frequency analysis of the effects of advertising is not plagued by serious endogeneity concerns. We re-address the link between advertising and stock markets by first analyzing the impact of daily TV and newspaper advertising expenditures on investor attention. To measure investor attention, we introduce a new proxy based on page views of the company's Wikipedia page. We provide clear evidence that abnormal advertising leads to a short-term increase in investor attention.

The existence of a positive influence of advertising on attention is a necessary but not a sufficient condition for advertising to also influence stock markets. Thus, we then investigate the impact of advertising on turnover, liquidity, and returns. Our analysis using daily data reveals a statistically significant positive impact of advertising on turnover. Furthermore, there is some evidence of a statistically significant positive impact of advertising on liquidity measured by the effective bid-ask spread. However, even when statistically significant, the effects are very small in terms of economic significance. Most importantly, we find no impact of advertising on short-term returns at all. Although this is a "non-result", we think this finding is important as it casts serious doubts on the conventionally held view that advertising is an efficient way to boost short-term stock market valuations.

Thus, our results are in conflict with the arguments in Chemmanur and Yan (2011) and Lou (2014), who find a positive relationship between changes in advertising and stock market returns in the same year. However, their studies are based on annual data and consequently could be subject to endogeneity problems. It is possible that firms that do particularly well within a year subsequently increase their advertising budgets for the rest of the year. In that situation, one would indeed find a positive relationship between advertising and contemporaneous stock market

returns on a yearly frequency without there being a causal impact of advertising on returns. We test this hypothesis by using panel vector autoregressions with returns and advertising as the components. Our results strongly suggest that returns are positively associated with future advertising within a year, but not the other way around. Thus, the positive correlation at the yearly level can likely be explained by reverse causality.

The main contribution of our paper is to provide evidence that advertising does indeed create attention among investors, but that managers are wrong in assuming that they can use advertising, e.g. around corporate events or insider transactions, to artificially increase the stock price in the short run.

In our empirical analysis, we use two new databases. The first database contains the number of page views of a firm's Wikipedia page aggregated on a daily level, which we use as a proxy for investor attention. The second database provides information on daily advertising expenditures of virtually all firms that advertise in a large sample comprising of all national newspapers and a large number of local newspapers, as well as most important local and national TV channels. To the best of our knowledge, this is the most comprehensive sample of advertising expenditures of U.S. firms with detailed information on advertising used in the literature so far. For the years 2007 to 2012, for which the two databases overlap, we find a very strong impact of advertising on Wikipedia page views after controlling for time- and firm-fixed effects. The impact lasts for several days and results obtain for newspaper as well as for TV advertising. Furthermore, they hold and are of virtually identical magnitude after controlling for the impact of important firm-related news like earnings announcements or coverage of the firm in newspapers, showing that our results are not driven by investor attention created by fundamental news.

Additionally, we find that advertising on a per dollar basis has a stronger impact on Wikipedia page views for advertising in business and news channels as compared to entertainment channels. This impact is also stronger for advertising in national newspapers (particularly in the Wall Street Journal) as compared to local newspapers, both suggesting that our proxy for attention does actually capture investor attention. Consequently, short-term advertising seems to be a good proxy for investor attention that is unlikely to be driven by fundamental news. We think this is a great advantage for studies trying to understand the impact of attention, as earlier proxies for attention are very closely linked or directly based on news about the firm. For example, Barber and Odean (2008) use news coverage, trading volume, and extreme one-day returns as attention proxies. Finally, we can also show that Wikipedia is a better proxy to capture attention than Google search volume (which is typically also only available for the very largest firms) and advocate to use the first in future research.

In the second main part of our analysis, we link our advertising data with financial markets data. Based on data from 1995 to 2012, we find a highly significant positive impact of TV as well as newspaper advertising on turnover on the same and the following one to three days. These findings are consistent with the idea that attention causes trading activity (Barber and

Odean (2008)). Looking at various advertising channels separately, we find no clear patterns, except that newspaper advertising in the Wall Street Journal tends to have the strongest impact on turnover. However, irrespective of the specific channel, the effects are not very important in terms of economic magnitudes, showing that the impact of advertising-induced non-news driven attention on stock markets is modest at best. Using TAQ data from 1996 until 2010, we find only very limited evidence of a positive influence of advertising on liquidity.

Most importantly, there is no impact of advertising on contemporaneous and subsequent daily returns. This result obtains independent of the specific advertising channel we look at. Even advertising in the Wall Street Journal or in business and news TV channels—which we could show to have the strongest impact on attention—has no impact on daily returns at all. Our findings also hold in cross-sectional sample splits based on firm characteristics and for firms with high and low media coverage.

In our last attempt to find the supposed short-term impact of advertising on returns, we then analyze firms where attention is more sensitive to changes in advertising. To do so, for each individual firm we first determine how strongly Wikipedia page views react to advertising. Then, we sort firms according to this advertising sensitivity into subsamples. We do find that turnover reacts stronger to advertising among high sensitivity firms. However, even among those firms there is no significant impact of advertising on returns.

Finally, to explain the differences between our findings and the results from the earlier literature showing a positive contemporaneous correlation between low frequency advertising and stock market returns, we conduct panel vector autoregressions with advertising and stock market returns using 12 monthly lags. We find that increases in returns predict future increases in advertising, but not the other way around. This suggests that reverse causality is an important explanation for the positive correlation between yearly advertising and stock returns observed in prior research.

Our paper complements the literature on the link between investor attention and stock markets. Barber and Odean (2008) document a positive impact of investor attention on buy-sell imbalances, arguing that attention leads to retail investor buying pressure. Similarly, Gervais, Kaniel, and Mingelgrin (2001) show that increased turnover affects the subsequent price of a stock. Consistent with these results, Da, Engelberg, and Gao (2011) find inflated stock prices during periods of increased investor attention and a subsequent reversal. They use the Google search volume index to capture investor attention.<sup>1</sup> Furthermore, Fang and Peress (2009) and Hillert and Ungeheuer (2015) find that increased media coverage leads to lower subsequent returns. We contribute to this line of the literature by using high frequency abnormal advertising as a new proxy for non-news driven investor attention and by showing that it increases turnover, but has no sizable effects on liquidity or short-term returns. Our proxy has the advantage that

<sup>&</sup>lt;sup>1</sup>Other papers that use Google search volume include Drake, Roulstone, and Thornock (2012) and Fink and Johann (2014).

it is available on a high frequency and is pre-determined at least a few days in advance, so that it is unlikely to be driven by fundamental news. Hence, we are better able to separate the effect of changes in the news environment from pure attention effects. We also contribute to the literature on attention methodologically by showing that easily available Wikipedia data is very reliable and available for a much larger number of firms than Google search volume. Our tests suggest that Wikipedia data is better able to capture investor attention than Google search volume.

We also contribute to the literature on advertising and attention. Other studies that use advertising as a proxy for investor attention are Grullon, Kanatas, and Weston (2004) and Lou (2014).<sup>2</sup> However, these studies use low-frequency advertising expenditures. Our study is the first to use a broad sample of high-frequency advertising expenditure data on attention and capital market variables, allowing us to make a big step towards establishing causality in the relationship between advertising and attention.<sup>3</sup>

Our study also informs the literature on the strategic use of advertising. Reuter and Zitzewitz (2006) and Focke, Niessen-Ruenzi, and Ruenzi (2015) show that firms can use advertising to influence media reports. In a financial context, besides the study of Lou (2014) cited above, there are other papers that argue that firms can use advertising strategically around IPOs and SEOs (Chemmanur and Yan (2009)), as well as M&A transactions (Hillert, Kunzmann, and Ruenzi (2015) and Fich, Starks, and Tran (2015)). Our results contribute to this literature by showing that managers might be wrong in believing that advertising helps to push up short-term valuations.

## 2 Data and Methodology

In this section, we first describe the financial markets data we use, including liquidity proxies based on high-frequency data and media coverage data (Section 2.1). We then introduce the Wikipedia page view data and define our measure for investor attention (Section 2.2). Finally, we introduce our advertising data set and our measures of (abnormal) advertising (Section 2.3). All variables are defined in detail in Appendix A.

 $<sup>^{2}</sup>$ Frieder and Subrahmanyam (2005) show a negative relationship between brand recognition and the share of institutional investors in a firm.

<sup>&</sup>lt;sup>3</sup>The only exception we are aware of is a contemporaneous paper that came to our attention after conducting our analysis: Madsen and Niessner (2014) document that Google searches are higher on days with print advertising of a company. However, our advertising measure is much more comprehensive by including print and TV advertising expenditures, with the latter clearly dominating overall advertising expenditures of firms. Furthermore, we use Wikipedia rather than Google ticker searches, which we later show is a much better proxy to capture attention.

### 2.1 Financial Markets, Analyst, and Media Coverage Data

Our initial stock market sample universe consists of all stocks in the NYSE/AMEX/NASDAQ (share code 10 or 11) Compustat/CRSP universe. Daily financial market data, specifically daily stock turnover, returns and market capitalization, are taken from CRSP's daily stock file. Return on assets and advertising-to-sales ratios as well as other balance sheet data are based on Compustat. Summary statistics for the sample period used in the analysis of the impact of advertising on attention (i.e., from 2007—the year in which our Wikipedia data starts, see Section 2.2—to 2012) are presented in Panel A.1 of Table 1. Panel A.2 shows summary statistics for the sample period used in the analysis of the impact of advertising on financial markets (from 1996 to 2010, the window for which we have TAQ data, see Section 2.3).

In our analysis of advertising's impact on liquidity in Section 4, we use Trade and Quote (TAQ) data which is available to us from 1996 to 2010. Specifically, we calculate the effective spread.<sup>4</sup> The effective spread is calculated as the daily transaction-weighted average of transaction prices relative to prevailing quote midpoints.

Finally, we obtain earnings announcement dates from I/B/E/S. The national media coverage dummy (Wall Street Journal, New York Times, Washington Post, USA Today) is based on LexisNexis data.<sup>5</sup> In robustness checks for our analysis of advertising's impact on investor attention, we use daily Google Search Volume (GSV) data for S&P 500 firms from 2005 to 2008 from Drake, Roulstone, and Thornock (2012). The authors report that daily data was largely unavailable for firms that are not part of the S&P 500 due to the truncation by Google. Summary statistics on the GSV data are presented in Appendix D, Table D2.

### 2.2 Wikipedia Page Views

We measure investor attention by using the daily number of page views of firms' Wikipedia pages (WIKI) for the time period from December 2007 (when Wikipedia data is first available) to December 2012. To our knowledge, we are the first to use WIKI data for a broad panel of firms.<sup>6</sup> On average, the Wikipedia pages of 2,019 distinct publicly listed companies are visited per day, generating 461,741 daily page views. The most similar alternative measure of investor attention is Google Search Volume (GSV), most prominently used by Da, Engelberg, and Gao (2011). WIKI—just as GSV—is a direct measure of attention, in contrast to financial market variables like trading volume or volatility, which are used in Barber and Odean (2008). This

<sup>&</sup>lt;sup>4</sup>We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014). In robustness checks reported in the appendix, we additionally use the relative spread, price impact and an intraday version of Amihud's illiquidity ratio, as well as order imbalances based on TAQ data.

<sup>&</sup>lt;sup>5</sup>We would like to thank Alexander Hillert for providing us with the media coverage data. This data set has also been used in Hillert, Jacobs, and Mueller (2014).

<sup>&</sup>lt;sup>6</sup>Moat, Curme, Avakian, Kenett, Stanley, and Preis (2013) use weekly page views for the 30 DJIA stocks. They aggregate firm-level page view counts for all 30 stocks each week to measure market-level investor attention and analyze a market timing strategy.

is an important feature of WIKI, since it allows us to disentangle the impact of advertising on investor attention from the subsequent impact on financial markets.

Additionally, WIKI has several advantages relative to GSV. First, it is available for a much broader set of firms on the daily level. GSV is only available above an unknown and time-varying threshold (set by Google), which leads to many missing observations for sparsely searched, usually smaller firms. We compare our WIKI data to the daily 2008 GSV data for S&P 500 firms provided by Drake, Roulstone, and Thornock (2012) and find that—even for these large firms—GSV is missing for 20.2% of firm-days. WIKI is never missing for these firms and nonzero for 95.4% of firm-days. This advantage should be even more important for the smaller, less visible non S&P 500 firms. Second, WIKI is a less noisy measure of investor attention. GSV data is usually collected for ticker symbols, because many company names are ambiguous (like 'Apple') and searches for these names are often unrelated to investor attention. However, even spikes in Google searches for ticker symbols can be unrelated to investor attention: For example, ISIS Pharmaceuticals, Inc. has the ticker symbol 'ISIS', which we believe has since 2014 mostly been searched by Google users interested in the terror organization, not the pharmaceutical company.

In contrast, our WIKI data is based on an unambiguous identification of a firm's Wikipedia page, so that we don't need to identify and exclude firms with ambiguous tickers. We have manually checked—e.g. via headquarter location and ticker symbol—that each page we use refers to the same firm we link the page with in CRSP/Compustat. For details on the procedure we use to extract Wikipedia page view counts, see Appendix B.1. Furthermore, product pages (e.g., for the beverage 'Coca-Cola') can usually be separated from firm pages (e.g., for the 'The Coca-Cola Company') in cases where one can plausibly assume that users might often search for the product rather than the company. This helps us to ensure that we are measuring investor attention instead of consumer attention. Third, WIKI is easier to interpret and comparable across firms and time, since it directly represents the number of page views for a firm's Wikipedia page. In contrast, GSV is scaled by the maximum search volume within a firm for each time window downloaded. Fourth, WIKI data reliably returns the same number of page views whenever it is downloaded, whereas GSV is calculated based on a randomly selected subset of search data, so that researchers downloading data at different points in time will work with different GSV measures. This problem is again particularly severe for smaller firms, that might or might not surpass the threshold mentioned above depending on the selected subset of search data.

Summary statistics in Table 1 confirm that WIKI data is available for a broad set of firms. 5,308 firms with common stocks (share code 10 or 11) listed on the NYSE, AMEX or NASDAQ have been part of the CRSP data set between December 2007 and December 2012 (Panel A). Panel B shows that 1,730 out of these 5,308 firms have WIKI and advertising data from Kantar (while GSV data is barely available for firms outside the S&P 500, see Drake, Roulstone, and

Thornock (2012)). As might be expected, the average market capitalization of firms with WIKI and advertising data is higher than the average for the full CRSP universe (\$7.5bn relative to \$2.8bn), because many of the firms without a Wikipedia page are very small. However, summary statistics on the GSV data—presented in Appendix D, Table D2—confirm that firms with available daily GSV data are substantially larger than those with available daily Wikipedia data (\$21.5b relative to the \$7.5b from Table 1).

Figure 1 shows the average weekly number of page views per company. Wikipedia page views are relatively stable from December 2007 until the end of 2009.<sup>7</sup> Since then, they steadily increase, showing that Wikipedia gained popularity as an information source on companies.

In Figure 2 we plot the average number of WIKI page views for firms by weekdays. We observe that page views are substantially lower during weekends. Thus, we do not use the number of page views directly, but normalize  $\ln(1+\text{WIKI})$  by subtracting the logarithm of one plus the median of WIKI on the same weekday during the last 8 weeks.<sup>8</sup> Abnormal WIKI for firm *i* on day *t* is thus defined as:

$$AWIKI_{i,t} = \ln\left(\frac{1 + WIKI_{i,t}}{1 + median_{k \in \{7,14,\dots56\}}(WIKI_{i,t-k})}\right)$$
(1)

This normalization is analogous to the normalization of GSV in Drake, Roulstone, and Thornock (2012) and Da, Engelberg, and Gao (2011) and captures deviations from a firmand weekday-specific benchmark.

#### 2.3 Kantar Advertising Data

Our advertising dataset is from Kantar Media and is similar to the data used in Focke, Niessen-Ruenzi, and Ruenzi (2015). The dataset starts in 1995 and ends in 2012. Kantar tracks advertising of public and private firms. They provide estimates for firms' advertising expenditures via all important marketing channels: TV (intradaily data), newspapers and magazines (daily), as well as internet, radio and outdoors / billboards (monthly). For TV and newspapers, these estimates are based on "rate cards" that indicate advertising prices depending, for example, on the length and timing of a TV spot or the size and day of the week of a newspaper advertisement. The high frequency of the TV and newspaper data enables us to cleanly identify effects of advertising. Advertising at lower frequencies (like Compustat's yearly advertising variable from financial statements) can be driven by the same latent factors that drive investor attention and financial market activity (omitted variable bias), or it can be directly caused by

<sup>&</sup>lt;sup>7</sup>The spike between May 17, 2008 and July 4, 2008 seems to be caused by data errors following the inclusion of other Wikimedia projects (e.g., Wikibooks.org, Wiktionary.org, etc) in the page count system. The negative spike in September 2009 is due to server failures at Wikipedia over several days in that month. Our main results are not affected if we exclude these time periods.

<sup>&</sup>lt;sup>8</sup>We use one plus the logarithm of the absolute number of page views to account for the strong skewness of the distribution of page views (see Table 1) and for days with zero page views.

them (reverse causality). In the short-run—typically per quarter, but at least within a couple of weeks—advertising is predetermined, which enables us to avoid these identification issues. We therefore focus on the TV and newspaper channels, which are available at the daily level.<sup>9</sup>

Kantar's newspaper advertising data covers a large proportion of newspaper advertising in the US. Kantar tracks all advertisements in 155 US newspapers, which include all four national as well as many important local newspapers. Total newspaper advertising expenditures tracked by Kantar from 1995 to 2012 are \$328bn, whereas the Newspaper Association of America (NAA) estimates a total of \$693bn for the entire newspaper industry from self-reported figures by newspaper publishing companies during this period. Thus, Kantar's tracking percentage for the whole period is nearly 50%. However, Kantar only began coverage of local newspapers in 1999. From 1999 to 2012, Kantar's tracking percentage is even higher at about 60%.

Kantar's TV advertising data covers 990 TV stations in 15 networks. In particular, it includes several news and business TV channels (CNN, CNBC, Fox News, MSNBC and CNN headline news). The total of TV advertising expenditures tracked by Kantar from 1995 to 2012 is \$1,299bn. To the best of our knowledge, Kantar is the most comprehensive source of TV advertising data. Nielsen, MagnaGlobal and eMarketer, three other companies that offer advertising tracking data, only provide significantly smaller ad expenditure samples. According to Kantar, TV (newspaper) advertising accounts for 59.25% (15.00%) of total advertising from 1995 to 2012. The development of advertising expenditures across the different media is shown in Figure 3. Throughout our sample period, TV is the dominant advertising channel.<sup>10</sup> Figure 4 shows the development of weekly TV and newspaper advertising. The graph reveals strong seasonalities (e.g., the yearly SuperBowl spike in TV advertising). It also shows that TV advertising expenditures have increased steadily since 1995, whereas newspaper advertising has decreased.

For our analysis of advertising's impact on investor attention and financial markets in sections 3 and 4 we do not use advertising dollars directly. Rather, in order to avoid omitted variable bias through correlations between persistent latent factors (e.g. visibility of a company's products to consumer) and our dependent variable, we first normalize advertising. Due to large differences in the nature of TV and newspaper advertising, we normalize these two channels' advertising expenditures differently.

TV advertising is dominated by continuous campaigns. The average length of subsequent strictly positive expenditures for daily TV advertising by a firm in our data set is 12 days. We run an AR(7) model of current TV advertising on lagged TV advertising. Results (see Table

<sup>&</sup>lt;sup>9</sup>We do not use data on magazine advertising, because magazines are published at lower frequencies (e.g., weekly or monthly) and are read throughout the time period in between issues. In contrast, TV spots are seen immediately and daily newspapers are mostly read on the same day. This allows us to attribute advertising to specific days more precisely.

<sup>&</sup>lt;sup>10</sup>This finding is confirmed by eMarketer, another ad tracking agency with a focus on digital marketing. According to their estimates, the percentage for TV (newspaper) advertising in 2012 was 39.1% (11.15%). See http://www.emarketer.com/Article/US-Total-Media-Ad-Spend-Inches-Up-Pushed-by-Digital/1010154

D3 in Appendix D) show that TV advertising expenditures from t - 1 are most relevant when predicting TV advertising in t. There is also a slightly increased coefficient estimate for TV advertising expenditures from t - 7, but its magnitude of the impact of TV advertising in t - 1is four to five times as large. Furthermore, Figure 5 shows that there are no strong weekday effects for TV advertising. Thus, in order to prevent highly correlated regressors across the different lags, we use simple log-differences as our measure of abnormal TV advertising:

$$AA(TV)_{i,t} = \ln\left(\frac{1 + TVAdv_{i,t}}{1 + TVAdv_{i,t-1}}\right).$$
(2)

In contrast, newspaper advertising is dominated by campaigns in which a firm advertises on the same weekday for several weeks, but not in between. We again run an AR(7) model of current newspaper advertising on lagged newspaper advertising. In this case, newspaper advertising expenditures of the same firm on the same day one week ago (t - 7) is by far the most important predictor of current advertising (see Table D3 in Appendix D). Its impact is nearly four times as large as the impact of advertising on the previous day. Moreover, Figure 6 shows that newspaper advertising differs strongly by weekday. For instance, advertising on Sundays is more than four times larger than on Mondays. We thus normalize (similar as in our normalization of AWIKI) by subtracting the logarithm of one plus the median of newspaper advertising on the same weekday during the last 8 weeks. Abnormal newspaper advertising for firm *i* on day *t* is defined as:

$$AA(NP)_{i,t} = \ln\left(\frac{1 + NewspaperAdv_{i,t}}{1 + median_{k \in \{7,14,\dots56\}}(NewspaperAdv_{i,t-k})}\right).$$
(3)

Summary statistics in Table 1, Panel B show that firms spend around \$80,000 (\$14,000) per day on TV (newspaper) advertising during the Wikipedia sample period from 2007 until 2012, confirming that TV is the dominant advertising channel. This is also the case for the TAQ sample period from 1995 until 2012.

Surprisingly, the correlation between AA(TV) and AA(NP) on a daily level is close to zero, suggesting that abnormal TV and newspaper advertising are not strongly related on a high frequency and both advertising channels should be taken into account.

To arrive at our final data set, we begin with all observations for which financial market data is available. We then merge this data with the control variables and information on advertising and WIKI (TAQ) in Section 3 (Section 4). For our analysis of investor attention, we include weekends, as investors can of course search for information on investment alternatives on Saturdays and Sundays, too. In order to mitigate the impact of outliers on our results, we require that a firm has positive advertising on at least one day within the previous eight weeks. Summary statistics on the firm-day level as used in our regressions can be found in Appendix D, Table D1 for the investor attention regressions and Appendix D, Table D6 for the financial markets regressions.

### **3** Advertising and Attention

### 3.1 Main Results

The ultimate goal of our empirical analysis is to test whether advertising affects important capital market variables like short-term turnover, liquidity, and in particular stock market returns. One necessary condition for such an effect is that advertising creates attention among potential investors in the first place. Thus, we start our empirical analysis by investigating whether advertising has an impact on investor attention as measured by the number of page views of a company's Wikipedia page. We focus on the Wikipedia page of the company itself rather than its products, which gives a cleaner proxy for potential investor attention (see Section 2).

Specifically, we regress daily abnormal Wikipedia page views for firm i on day t,  $AWIKI_{i,t}$ , on abnormal advertising of firm i on the same day,  $AA_{i,t}$ , as well as three lags of abnormal advertising, controls lagged by seven days, and the seventh lag of the dependent variable:<sup>11</sup>

$$AWIKI_{i,t} = \alpha + \beta_0 \cdot AA_{i,t} + \sum_{j=1}^3 \beta_j \cdot AA_{i,t-j} + \gamma \cdot Controls_{t-7} + \delta \cdot AWIKI_{i,t-7} + \epsilon_{i,t}.$$
 (4)

All regressions include firm fixed effects (to control for firm-specific increases in WIKI and advertising) and week fixed effects (to control for time trends in changes in WIKI and advertising). Furthermore, Wikipedia page views vary substantially depending on the day of the week (with much lower levels of page views on weekends; see Section 2.2). Although our normalization of WIKI should already partly control for this, we also include day-of-week fixed effects to purge any remaining weekday effects. We include the seventh lag of the dependent variable to account for a possible time-varying, firm-specific mean-reversion level that is not captured by control variables or time fixed effects. We use the seventh—instead of the first—lag of the dependent variable and the controls in order to avoid endogeneity with the lags of abnormal advertising: Lagged advertising may impact these variables directly and we want to capture direct and indirect effects of abnormal advertising on the contemporaneous dependent variable jointly. Standard errors are clustered by firm. All firm-day observations with positive advertising spending on any day within the previous eight weeks are included in the regression. Results using abnormal advertising on TV, AA(TV), as independent variable but not including any

<sup>&</sup>lt;sup>11</sup>Including the lagged dependent variable *and* firm fixed effects can lead to biased estimators in panel regressions (Nickell (1981)). However, this problem is only relevant in short panels. Our panel encompasses 1,836 days and including the lagged dependent variable is thus unproblematic in our context. Not including the lagged dependent variable also leads to very similar results.

controls are shown in Column (1) of Table 2.

We find a highly significant positive impact of contemporaneous abnormal advertising on page views. The effect is statistically significant at the 1%-level. The effect of lagged advertising on days t - 1 to t - 3 is also positive and highly significant, with coefficient estimates being even higher than for contemporaneous abnormal advertising. A slightly lower coefficient of the contemporaneous impact of TV advertising makes sense, as some advertising might be aired only late on the day and viewers might often not have enough time to react on the same day by looking up the firm. The coefficient estimate is smaller for the impact of abnormal advertising on day t - 3, but still substantial.<sup>12</sup> These findings show that the attention effect emanating from advertising lasts at least for a couple of days. A lasting impact of advertising on behavior over several days is consistent with evidence from the marketing literature.<sup>13</sup>

In column (2) we run the same regression, but use contemporaneous and lagged abnormal advertising in newspapers, AA(NP), as independent variable. Results show a very similar pattern as before. We again find a positive impact of abnormal advertising on page views and the effect is statistically significant at the 1%-level for contemporary as well as all three lags of abnormal advertising. Now, the highest estimate is observed for contemporaneous advertising and decreases for lagged advertising. The fact that we now find the strongest impact of contemporaneous advertising also makes intuitive sense, as most newspapers appear in the morning and readers still have the full day to react.

The daily frequency of our data and the rich fixed effects that we include allows us to mitigate endogeneity concerns to a large extent. Earlier studies face problems of reverse causality and are potentially plagued by omitted variables due to their focus on yearly advertising and its impact on contemporaneous attention or capital market outcomes. As advertising is pre-determined at least in the short term, it is very unlikely that advertising would be increased on a specific day because the firm observed that attention has increased. However, there is one remaining endogeneity concern: it is possible that firms strategically advertise more around corporate news events that are known sometime in advance to them and which they expect to trigger attention. Furthermore, Focke, Niessen-Ruenzi, and Ruenzi (2015) show that firms that advertise more are covered by newspapers more frequently. Thus, our results could be driven by increased news coverage that eventually causes attention (and is positively correlated with advertising) rather than by advertising itself.

To address these concerns, we add dummy variables indicating whether there was an earnings announcement for firm i on day t,  $EA_{i,t}$ , and whether there was a newspaper article about firm i on day t,  $News_{i,t}$ . There might be other news events that create attention and that no

 $<sup>^{12}</sup>$ If we include further lags, estimates of the effect of one-day increases in advertising become smaller and eventually insignificant.

<sup>&</sup>lt;sup>13</sup>For example, Aravindakshan and Naik (2010) find that the impact of product advertising on brand awareness can last for up to three weeks and Hill, Lo, Vavreck, and Zaller (2013) show that the impact of political advertising decays more quickly but still lasts for at least several days.

newspaper writes about and that are not associated with earnings announcements. However, even if that is the case, our variables should capture at least the largest part of news-driven attention. Thus, if the effect we observe is really driven by strategic advertising around attention inducing news events, we should at least see a very substantial reduction in our coefficient estimates after controlling for such news events. In columns (3) and (4) we repeat the same regressions as in columns (1) and (2) but include the two event dummies. We also include further control variables to capture firm characteristics like previous turnover, previous return, and previous realized stock market volatility over the four week period ending one week prior to the day of the respective observation and firm size on day t - 7 as an additional controls.

As expected, we find a very strong positive impact of our two event dummies, EA and News, on AWIKI. Both coefficient estimates are positive and highly statistically significant at the 1%-level, showing that AWIKI is also a very good proxy for news-induced attention by investors. However, the impact of our abnormal advertising variables, AA(TV) and AA(NP), on attention is not affected at all by the inclusion of the news event dummies. They all remain highly significant and the economic magnitude of the coefficient estimates is virtually identical. As the two dummies added in these regressions should certainly capture the most important news events, not even observing a reduction in coefficient estimates for the impact of abnormal advertising strongly suggests that our results are not driven by high abnormal advertising around news events that create attention.

In column (5) we add both variables, AA(TV) and AA(NP), as well as the full set of controls in the same regression.<sup>14</sup> Coefficient estimates for both sets of variables are virtually unchanged as compared to the results from column (3) and (4), respectively. This pattern shows that there is no strong correlation between abnormal advertising in newspapers and on TV, that is, not many firms seem to spend more advertising dollars at the same time for newspaper advertisements and for TV spots. Indeed, the correlation between  $AA(TV)_{i,t}$  and  $AA(NP)_{i,t}$ is 0.0022.

The size of the coefficient estimate for the impact of the AA variables can also be interpreted economically. As they are measured as natural logarithm and AWIKI is also a natural logarithm, we can directly interpret the coefficient estimate as an elasticity. Based on column (5), we find that increasing abnormal newspaper (TV) advertising by one standard deviation on a specific day leads to an increase in abnormal page views of 0.408% (0.186%) on the same day. To put these numbers into perspective, they can be compared to the impact of major news events like earnings announcements. The impact of EA in column (5) is 0.09738, i.e., page views on an earnings announcement day are 9.74% higher than on other days. Similarly, on a day with corporate news that a newspaper reports about, page views are 8.68% higher.

<sup>&</sup>lt;sup>14</sup>The number of observations in this regression is somewhat larger than in columns (1) through (4). This increase is driven by the requirement that a firm needs to have positive advertising in the previous eight weeks *either* on TV *or* in newspapers in these cases, while in column (1) and (3) ((2) and (4)) we require positive advertising on TV (in newspapers).

While the impact of EA and NEWS is clearly much larger than the impact of a one standard deviation increase in daily advertising expenditures, one has to bear in mind that earnings announcements only happen four times per year and the average firm in our sample is covered on only 6.6 days per year in a newspaper article, while advertising occurs on a daily level and large percentage changes in advertising from one day to the next happen very frequently (see Table D1 in Appendix D).

While the coefficient estimates for the impact of lagged abnormal advertising on TV and in newspapers are somewhat larger for TV but generally of comparable magnitude, one has to bear in mind that the amount of advertising dollars spent on TV is a magnitude larger than the amount spent on newspaper ads; while the firms in our sample spend on average 14,108 USD per day for newspaper advertising, this number is nearly six times as large (79,846 USD) for TV advertising (see Table 1, Panel B). Thus, on a per-dollar basis, newspaper advertising has a stronger impact than TV advertising. For example, a 100,000 USD increase in advertising expenditures (which is a little bit more than the average daily aggregate advertising expenditures in TV and newspapers of the firms in our sample) leads to an increase of 0.034% for TV advertising and 0.186% for NP advertising.

Finally, in column (6) we look at an alternative proxy for attention that has been used in the finance literature before, namely Google search volume for a company ticker. To check whether this proxy is also suitable to capture (non-news driven) attention, we replace our dependent variable from the regression in column (5) by the abnormal Google search volume index,  $ASVI_{i,t}$ , from Drake, Roulstone, and Thornock (2012). We still observe a highly significant impact of EA and News, but the coefficient estimate is slightly (substantially) reduced for the impact of earnings announcements (newspaper articles) as compared to our previous results.<sup>15</sup> More importantly in our context, the impact of advertising on Google search volume is only significant for contemporaneous newspaper advertising and its first lag, while it is virtually always insignificant for the impact of TV advertising. This finding shows the advantage of using Wikipedia page views as a much more precise measure of attention than Google search volume (as explained in more detail in Section 2).

A potential endogeneity problem might be strategic scheduling of advertising for day t in anticipation of effects of earnings announcements or, more generally, corporate news on that day. Although we already control for these events using our two event dummies, to further alleviate such concerns, we reproduce our main results excluding firm-day observations when there is an earnings announcement or national newspaper article in the time window from three days before to three days after the current period. Results are qualitatively the same and quantitatively similar for both TV and newspaper advertising (see Appendix D, Tables D5).

<sup>&</sup>lt;sup>15</sup>The economic magnitude of the impact of earnings announcement days and national newspaper articles on  $ASVI_{i,t}$  is comparable to results from Drake, Roulstone, and Thornock (2012).

### 3.2 Advertising Channels

So far, we show that advertising on TV as well as in newspapers generally has a strong impact on attention. We now examine different advertising channels in more detail. Specifically, with regard to TV advertising, we distinguish between advertising in news and business channels and other TV channels, expecting a stronger effect for the first. With regard to newspaper advertising, we distinguish between advertising in local and national newspapers and specifically look at the Wall Street Journal, which is presumably the most important national newspaper for investors.

We start by splitting up TV advertising into advertising on CNN, CNBC, Fox News, MSNBC and CNN headline news and advertising on all other TV channels. The first channels are news or business channels, while the other channels mainly include pure entertainment channels. It is plausible that potential investors are more likely to watch news and business channels than other channels. However, the amount of advertising dollars spent on spots in these channels is much lower (see Table 1, Panel B). Thus, still finding an impact of advertising on AWIKI even in this case would strongly reinforce our prior evidence that advertising also creates attention among potential investors. The results are presented in Table 3.

In column (1) we present results from the same regression as in column (3) from Table 2, but calculate abnormal advertising only based on advertising dollars spent by the firm in one of the news or business channels, AA(TVNWS). We still find a highly significant positive impact of current abnormal advertising and its lags on AWIKI. The coefficient estimates are even slightly larger than in Table 2. In column (2) we calculate abnormal advertising based on advertising in all other TV channels, AA(TVNONWS). Results are again similar, but now coefficient estimates are slightly smaller than before. In column (3) we include both abnormal advertising variables, AA(TVNWS) and AA(TVNONWS), in one regression. The impact of all abnormal advertising variables is now slightly reduced in economic terms as compared to column (1) and (2), respectively. However, they are still all highly significant and the impact of AA(TVNWS) is still higher than that of AA(TVNONWS), meaning that doubling advertising expenditures on news channels has a larger impact on the percentage increase in our attention proxy than doubling advertising expenditures on non-news channels. This pattern becomes much stronger, if we look at advertising on per dollar basis again. Firms spend on average 1,114 USD per day on advertising in news channels and 78,723 USD per day on advertising in all other channels (see Table 1, Panel B). These patterns show that the impact of an increase in abnormal advertising on a per dollar basis is more than 80 times as large for news channels than for other channels. This further supports the view that AWIKI is a good proxy for investor attention. Moreover, it also shows that firms trying to attract investor attention should focus their advertising on news channels. Increasing advertising expenditures on news and business (entertainment) channels by 100,000 USD leads to an increase in page views for the respective

company by 0.466% (0.027%).

Looking at newspapers, we find a similar pattern. Here, we first split up newspapers into local and national newspapers, where the latter comprise of the New York Times, USA Today, the Washington Post, and the Wall Street Journal (WSJ). Results for the impact of abnormal advertising in local and national newspapers, AA(NPLOC) and AA(NPNAT), are presented in columns (1) and (2) of Table 4.

In both cases, current and lagged abnormal advertising have a highly significant positive impact on AWIKI. Overall, the coefficient estimates are of similar size; while the impact of contemporaneous abnormal advertising and its second lag are stronger for national papers, the first and third lag of abnormal advertising is stronger in local newspapers. However, once we take into account that the average firm advertises nearly five times as much per day in local newspapers than in national newspapers (see Table 1), we can conclude that the impact of advertising is economically much stronger for national than for local newspapers on a per dollar basis. While it seems plausible that investors rely on national newspapers more than on local newspapers, we dig deeper into this issue by splitting up abnormal advertising in national newspapers into abnormal advertising in the Wall Street Journal, AA(NPWSJ), and in the other three national newspapers, AA(NP3NAT). Results are presented in column (3). Although AA(NPWSJ) only captures advertising in one individual newspaper, we still find some significant effects. The impact of contemporaneous abnormal advertising and the second lag (first lag) are still statistically significant at the 1% (10%) level. Very similar results are obtained once we also include local newspaper advertising in the regression again in column (4). The coefficients are of similar size for the Wall Street Journal, other national and local newspapers. However, this only shows how much AWIKI changes in response to percentage changes in advertising. Since average advertising expenses are quite different across the different newspapers, the per-dollar impact differs as well. For instance, consider an equally large increases in dollar terms, e.g. by 100,000 USD, in the three types of newspapers. For local newspapers, this implies an increase of only 0.16%, while it implies an increase of 0.37% and 0.41% for the Wall Street Journal and the other national newspapers, respectively. This shows that the impact of advertising in national newspapers including the Wall Street Journal is much larger on a per-dollar basis than in local newspapers.

### 3.3 Stability Tests

We now investigate the robustness of our above findings by looking at cross-sectional sample splits, assessing the temporal stability of the relationships, and using alternative advertising definitions. All results mentioned below are presented in Table D4 in Appendix D.<sup>16</sup>

We begin with two sample splits intended to capture the degree of visibility of the firm to

<sup>&</sup>lt;sup>16</sup>A more detailed discussion of the results form the stability tests is contained in Appendix B.2.

viewers, readers, as well as potential investors. We split the sample into consumer and nonconsumer firms, as well as by firms' media coverage over the last 12 months. We find that the positive effect of advertising on investor attention always remains significantly positive. It is stronger for low-visibility firms, defined as non-consumer and low media coverage firms.

In further stability tests, we split our sample period into the earlier years 2007 to 2009 and the later years 2010 to 2012. We also replace our abnormal advertising measures by more coarse and endogeneity-prone advertising measures, namely the logarithm of 1 plus the dollar amount spent on advertising by the respective firm, Log(1 + Ad\$), and a dummy variable that takes on the value one, if the firm spent at least one USD on advertising on the respective day,  $I_{Ad\$>0}$ . We can confirm our earlier findings in each case. Hence, our results are stable over time and robust with respect to the advertising measure we use.

Overall, our results provide evidence that advertising does create attention. The stronger impact of advertising in national newspapers and the WSJ and in news- and business TV channels clearly suggests that Wikipedia page views are a good way to capture attention not only in general, but among potential investors in particular.

# 4 Advertising and Financial Markets

### 4.1 Main Results

Having established the impact of advertising on investor attention, we now analyze the impact of advertising on turnover, liquidity, and returns. Turnover is measured by the log of daily trading volume, scaled by shares outstanding. Our liquidity measure is the log of effective spread, based on TAQ-data.<sup>17</sup> Returns are measured in excess of that day's market return, constructed from the Fama-French model's market-return factor. Similar to the analysis for investor attention, we regress each dependent variable for firm i on day t,  $DV_{i,t}$ , on daily contemporaneous abnormal advertising,  $AA_{i,t}$ , as well as lags of abnormal advertising, controls and the seventh lag of the dependent variable.<sup>18</sup>

$$DV_{i,t} = \alpha + \beta_0 \cdot AA_{i,t} + \sum_{j=1}^3 \beta_j \cdot AA_{i,t-j} + \gamma \cdot Controls_{t-7} + \delta \cdot DV_{i,t-7} + \epsilon_{i,t}.$$
 (5)

All regressions include firm fixed effects (e.g. to control for permanently higher turnover of firms with persistently increasing advertising expenditures) and week fixed effects (to control for market-wide time trends, e.g. business-cycle effects). Furthermore, we include day-of-week

<sup>&</sup>lt;sup>17</sup>For more detailed variable descriptions, see Section 2 and the variable description in Appendix A.

<sup>&</sup>lt;sup>18</sup>Including the lagged dependent variable *and* firm fixed effects can lead to biased estimators in panel regressions, see Nickell (1981). However, this problem is only relevant in short panels. Our panel regressions use a minimum of 3,777 trading days and including the lagged dependent variable is thus unproblematic in our context.

fixed effects to control for intra-weekly seasonalities. For example, turnover and liquidity tend to be lower on Mondays (Gallant, Rossi, and Tauchen (1992)). We include the seventh lag of the dependent variable to account for a possible time-varying, firm-specific mean-reversion level that is not captured by control variables or time fixed effects. Control variables and the dependent variable are lagged by 7 days instead of 1 day in order to avoid endogeneity with the lags of abnormal advertising: Lagged advertising may impact these variables directly and we want to capture direct and indirect effects of abnormal advertising on the contemporaneous dependent variable jointly. Again, reverse causality or omitted variable bias should not be problems for our analysis since advertising is programmed more than a week before it is broadcast. Standarderrors are clustered by firm and we require firms to have advertised at least once during the last eight weeks to be included in the regression. Results for abnormal TV advertising, AA(TV) are shown in Table 5.

In Column (1), we find a positive impact of TV advertising on turnover. The effect is statistically significant at the 5%-level. The impact of lagged TV advertising is also significant and larger than that of contemporaneous advertising, i.e., an TV advertising campaign starting yesterday has a larger effect on today's turnover than on yesterday's turnover, probably because a lot of investors do not trade in response to an ad until after trading closes. However, the effect seems to be short-lived, since a campaign starting two or three days ago has a smaller effect on today's turnover than campaigns starting today or yesterday. Furthermore, the effect of TV advertising on turnover is quite small in economic terms: A one standard deviation increase in AA(TV) increases turnover by 0.10% contemporaneously and by 0.12% on the following day. For comparison: National newspaper coverage about a firm goes along with 15.95% more turnover on the same day and there is around 49.72% more trading on earnings announcement days.<sup>19</sup>

The coefficient estimates for the impact of TV advertising on illiquidity in Column (2) is negative, but only statistically significant at lags two and three. This is consistent with an increase in noise trading due to product market advertising. Increased noise trading lowers adverse selection costs, so that liquidity improves.<sup>20</sup> Grullon, Kanatas, and Weston (2004) find that firms' advertising expenditures on the yearly level are contemporaneously positively correlated with liquidity, which is consistent with our results. However, relative to their results, the economic significance we measure is small. A one standard deviation increase in AA(TV)leads to a reduction in the effective spread of 0.11%.<sup>21</sup> As an illustration, the estimated effect

<sup>&</sup>lt;sup>19</sup>In comparing these numbers it should be noted that advertising varies on a daily level, whereas national newspaper coverage (on average less than 14 days per year, standard deviation of 0.22, see Table D6 in Appendix D) and earnings announcements (four times per year, standard deviation of 0.12) happen infrequently. However, even the respective one standard deviation impacts of  $0.22 \cdot 16\% = 3.51\%$  (newspaper coverage) and  $0.12 \cdot 50\% = 5.97\%$  (earnings announcements) are by magnitudes larger than the impact of abnormal advertising.

<sup>&</sup>lt;sup>20</sup>According to the model of Barber and Odean (2008) liquidity should rather decrease due to increased inventory holding costs after attention-induced order imbalances.

<sup>&</sup>lt;sup>21</sup>For comparison: Grullon, Kanatas, and Weston (2004) estimate an elasticity of relative spreads w.r.t.

on a stock with an effective spread of 100 basis points is an order of magnitude less than 1 basis point. Hence, consistent with a small increase in noise trading activity, liquidity improves slightly.

We now analyze the impact of TV advertising on stock prices. One might expect an increase in prices due to attention-induced buying after increased advertising: Consistently, Lou (2014) finds a strong contemporary positive correlation between advertising and returns on the yearly level, and interprets his findings as evidence for a *short-term* price impact of advertising. A short-term price impact of advertising should become even more visible at higher frequencies, since the price impact and reversal periods can be clearly separated. However, we find virtually no impact of TV advertising on returns in Column (3) of Table 5. The only significant coefficient is for the second lag of AA(TV) and implied a return effect of 0.002% for a one standard deviation change in TV advertising, which is less than a quarter of a basis point.<sup>22</sup> The absence of a temporary price increase is consistent with our finding that liquidity does not decrease after TV advertising.

Results for newspaper advertising, AA(NP) are shown in Table 6. As for TV advertising, we find a statistically significant, positive impact of newspaper advertising on turnover, see column (1). The impact is significant at the 1%-level. Again, there are lagged reactions to advertising: Increased advertising yesterday and the day before have a stronger impact on today's turnover than contemporaneous newspaper advertising. The effect is short-lived, since it becomes insignificant at higher lags. The standard deviation of AA(NP) is 3.01, so that a one standard deviation increase in abnormal newspaper advertising today leads to  $3.01 \cdot 0.032\% =$ 0.10% more contemporary turnover and  $3.01 \cdot 0.050\% = 0.16\%$  more turnover two days from today. As for TV advertising, this economic effect is one to two orders of magnitude below the estimates for earnings announcements and national newspaper coverage. Thus we find a statistically significant, but economically small effect of newspaper advertising on turnover.

The effect of newspaper advertising on illiquidity is negative for days t-1 to t-3 (see column (2) in Table 6), but only statistically significant at the second lag. The economic significance remains small: the largest impact is  $3.01 \cdot (-0.039\%) = -0.12\%$ , which implies a change in effective spread an order of magnitude below one basis point for a stock with an effective spread of 100 basis points. As for TV advertising—and again consistent with a small increase in noise trading activity—liquidity improves slightly.

The impact of newspaper advertising on returns (see column (3)) is always insignificant and coefficient estimates are even smaller than for TV advertising, confirming our earlier results.

A potential endogeneity problem might be strategic scheduling of advertising for day t in

Compustat's advertising of -4.7% for the years 1993 to 1998.

 $<sup>^{22}</sup>$ It is possible that advertising has a signalling effect in addition to an attention effect. Given that advertising is predetermined, however, the information on advertising is likely known in advance and should therefore be incorporated into prices before the ad airs on TV. We therefore conclude that the lack of a short-term price impact of advertising can likely not be explained by signalling.

anticipation of effects of earnings announcements or, more generally, corporate news on that day. Although we already include dummies to capture the impact of such events on our dependent variables, to further alleviate such concerns, we now also reproduce our main results excluding firm-day observations when there is an earnings announcement or national newspaper article in the time window from three trading days before to three trading days after the current period. Results are qualitatively the same and quantitatively similar for both TV and newspaper advertising (see Appendix D, Tables D12 and D13).

Overall, we find a significantly positive impact of product market advertising on turnover. The effect is economically small and additional trading seems to increase liquidity, rather than decreasing it. Most importantly, we find virtually no short-term price impact of advertising. Our results show that firms can not use advertising to easily influence short-term stock returns. However, our findings hitherto are based on all advertising expenditures in TV and Newspapers. Thus, in the next section, we dig deeper by checking whether can at least document an impact if we focus on cases where we are most likely to find a reaction.

### 4.2 Advertising Channels

Although we find that the impact of general product market advertising on financial markets is economically small, it may still be that advertising that is more visible to investors has a larger impact. To test this idea, we now turn to an analysis of subsets of our advertising channels (similar as in our analysis of investor attention in Section 3.2): we distinguish news and business channels from all other TV channels and consider the Wall Street Journal as well as other national and local newspapers separately.

We begin our analysis by regressing our dependent variables on measures of abnormal news and business channel advertising, AA(TVNWS), and abnormal advertising in all other channels, AA(TVNONWS). The set of control variables and fixed effects is the same as in Section 4.1. Table 7 presents the results. Column (1) shows that the effect of advertising on turnover is consistently positive across the two measures. However, only the contemporaneous effect of AA(TVNONWS) is significant. When we consider the dollar impact associated with the coefficient estimates, the effect of contemporaneous advertising on turnover is of similar magnitude for both types of channels, while the effects associated with lags of advertising are substantially larger for AA(TVNWS) than for AA(TVNONWS). Therefore, it is possible that the insignificant results on AA(TVNWS) are caused by insufficient power to measure such a small effect or noise in the variable due to the low overall dollar level.

For illiquidity, we find a substantially stronger effect both in statistical and economic terms for AA(TVNWS) than for AA(TVNONWS). As can be seen in column (2), the coefficients on lags one to three of AA(TVNWS) are significant at least at the 5% level. Except for lag two, which is significant at the 10% level, AA(TVNONWS) is insignificant. The economic significance of all coefficients on AA(TVNWS) is substantially higher in absolute terms than for AA(TVNONWS). For instance, the coefficients on the first lag in column (2) imply that a campaign starting on day t-1 and increasing abnormal advertising in news and business (other) TV channels by one standard deviation is associated with a decrease in  $EffSpr_t$  by -0.29% (-0.12%). Considering an equally large increase in dollar terms, e.g. by 100,000 USD, in both news and business (other) TV channels is associated with a decrease in  $EffSpr_t$  by -0.89% (-0.029%). This suggests a substantially stronger effect of news and business TV advertising on illiquidity. Although the results that the effect for advertising in news and business channels is stronger than that of advertising in the other channels is plausible, it should be noted that the economic significance is still small in both cases since 100,000 USD in news and business channel advertising is far above its mean (2,300 USD).

When we investigate the effect on returns, we find no effect of either AA(TVNWS) or AA(TVNONWS) (see column (3)), consistent with our earlier result that return effects are negligible, i.e., even advertising via channels that are more likely to be seen by potential investors (and that we show in Section to trigger more investor attention) do not lead to a measurable return effect.

Next, we study the effect of advertising in specific newspapers by computing abnormal advertising separately for the Wall Street Journal, AA(NPWSJ), the other three national newspapers (New York Times, USA Today, Washington Post), AA(NP3NAT), and for all local newspapers AA(NPLOC). Advertising in the Wall Street Journal (the other three national newspapers) is about 5 (4) times smaller than aggregate advertising in the 151 local newspapers, so that the coefficients should again be interpreted in dollar terms. Results are presented in Table 8

Column (1) shows that the effect on turnover is strongest for AA(NPWSJ). For lags one to three, the coefficient on AA(NPWSJ) is significant at least at the 5% level, whereas it is insignificant for the other three national newspapers and significant to a similar extent for the local newspapers. Except for the contemporaneous effect, the coefficients on all lags of advertising are largest for AA(NPWSJ). For instance, the coefficients on the first lag imply that doubling the amount of advertising spent in the Wall Street Journal (local) newspapers is associated with an increase in turnover by 0.07% (0.03%). Since five times less advertising dollars are spent in the Wall Street Journal alone compared to all local newspapers, this effect is strongly reinforced and clearly shows that the impact on turnover is strongest for AA(NPWSJ).

We find no significant impact of AA(NP3NAT) or AA(NPLOC) on illiquidity (see column (2)). For AA(NPWSJ), the coefficients are negative, but not significant, for the contemporaneous effect and the first two lags. In the third lag, we observe a positive coefficient that is significant at the 1% level. This suggests that illiquidity increases following an increase in advertising in t-3. Given that the other coefficients are consistently negative, we conclude that there is also no strong effect of AA(NPWSJ) on illiquidity.

Results for the impact of newspaper advertising on returns are presented in column (3).

We observe no statistically significant impact of abnormal advertising in the three national newspapers on returns, a positive (at the 5% level) impact of yesterday's advertising in local newspapers on today's returns and a counter-intuitive negative impact of yesterday's advertising in the Wall Street Journal. However, even for these cases the economic magnitudes of the effect is negligible.

The above results suggest a larger impact of news and business media advertising on illiquidity (for TV) and turnover (for newspapers). There is no strong difference between the different advertising channels for returns (for both media), turnover (for TV) and illiquidity (for newspapers). Importantly, our results show that even for news and business media advertising, which is more likely to reach investors, the size of the effect on financial market outcomes is small at best and clearly non-existent regarding returns.

### 4.3 Advertising Sensitivity

In an last attempt to document any strong impact of advertising on financial markets, we now turn to cross-sectional differences between firms. It may well be that the effects of advertising differ by firm. For example, some firms might be relatively unknown to investors ex-ante or might have particularly effective marketing plans so that advertising is more effective in attracting investor attention for them. We will study some of these determinants analyzing cross-sectional sample splits based on observable firm characteristics in our following robustness tests (Section 4.4). In this section, we take a more general approach by *estimating* the advertising sensitivity of each firm's investor attention directly and then splitting the sample based on this sensitivity. This approach offers the advantage that we do not require the identification of observable characteristics that determine the sensitivity of the firm's investor attention to advertising. To estimate firms' advertising sensitivity, we regress AWIKI on contemporaneous advertising as well as its first three lags, the full set of control variables, the seventh lag of the dependent variable, and day-of-week fixed effects. These regressions are computed for TV and newspaper advertising separately to allow advertising sensitivity to differ by medium. To reduce the noisiness of our results, we require at least 50 observations on a firm. This results in valid estimates for 998 (1098) firms in the TV (newspaper) regressions. The lower number of estimates for TV is due to some firms not advertising on TV. We define the advertising sensitivity for each firm as the sum of the four advertising coefficients. We then split the sample at the median of the estimated sensitivity and run the same regressions as in Section 4.1. We expect the effect of advertising to be stronger in the high advertising sensitivity group. In Table 9, we present results from this sample split for TV advertising.

Panel A shows that there is no significant impact of advertising on turnover, illiquidity or returns in the low sensitivity group. Panel B presents the results for the high sensitivity group. For turnover, column (1) shows that the coefficients are slightly larger than for low sensitivity firms for lags two and three and significant at the 5% level for lag 3. For illiquidity, column (2) shows that the coefficients on advertising are always larger (in absolute terms) in the high sensitivity group. For lags one to three, they are significant at least at the 10% level. For turnover and illiquidity, our results therefore appear somewhat stronger for high advertising sensitivity firms compared to low sensitivity firms. However, the confidence intervals are quite wide and often overlapping. For instance, the 10% confidence interval for the first lag of AA(TV) on EffSpr, where the difference is strongest, is [-0.00122, 0.00081] in the low sensitivity sample (see Panel A, column (2)) and [-0.00267, -0.00013] in the high sensitivity sample (see Panel B, column (2)). Moreover, even the largest effects accommodated by our results are still economically small. The lower bound of the interval in the high sensitivity sample, -0.0027, implies that a campaign starting yesterday with a one standard deviation increase in AA(TV) is associated with a decrease in EffSpr by  $2.28 \cdot (-0.27\%) = -0.61\%$ .

For returns, we only find the coefficient on the second lag to be positive and significant at the 10% level (see column (3)). However, even in this case the coefficient is very small in magnitude, implying an impact of a one standard deviation change in advertising on returns of 0.005%. Thus, we conclude that the advertising effect appears to be somewhat stronger for high sensitivity firms, but even in the high sensitivity group, where we would expect the strongest effect, the impact of advertising on financial market outcomes remains small and meaningless with respect to returns.

Next, we conduct the same sample split for newspaper advertising. The results are presented in Table 10. Panel A shows that we find virtually no effect of advertising on our dependent variables in the low sensitivity group. In the high sensitivity sample (Panel B), we find strong effects for contemporaneous advertising as well as for the first and second lag on turnover (see column (1)). All four advertising coefficient estimates are larger than in the low sensitivity sample. Column (2) shows that we do not find larger effects on illiquidity for high advertising sensitivity firms. Most importantly, for returns all coefficients are still insignificant (see column (3)).

Focusing on those firms with high advertising sensitivity, we therefore find stronger effects for liquidity (for TV) and turnover (for newspapers), but no differential effect for returns. This result is consistent with Section 4.2, where we find a stronger effect of news compared to nonnews TV channels with respect to liquidity and of the Wall Street Journal compared to other newspapers with respect to turnover. However, even the strongest effects we estimate for the high advertising sensitivity subgroup of firms are still economically small and even among those there is no impact of advertising on short-term returns at all.

#### 4.4 Stability Tests and Further Results

We now perform stability tests by splitting the sample based on observable firm characteristics. We also test the robustness of our results when TV and newspaper advertising are jointly included in the regression, with respect to temporal splits, splits by trading venues, the use of other measures of advertising, alternative liquidity proxies and Fama-MacBeth (1973) regressions for returns. Furthermore, we show that neither order imbalances nor volatility are significantly increased by advertising, which is consistent with our small estimates of the effects of advertising on liquidity and returns. The regression specifications remain the same as in Section 4.1. All results are presented in Tables D8 to D17 in Appendix D. A detailed description of results for sample splits, joint estimation of TV and newspaper advertising effects, and alternative advertising measures can be found in Appendix B.3.

We begin with various sample splits intended to capture the degree of visibility of the firm to viewers, readers and investors. We split the sample according to analyst coverage, firms' media coverage over the last 12 months, and consumer versus non-consumer firms. Our main results are stable, both for TV and newspaper advertising. We find mostly positive effects of advertising on turnover and liquidity, and we can reject economically significant effects of advertising on liquidity and returns. Hence, even if we specifically look at firms for which financial markets might be more advertising-sensitive, effects remain economically small.

In additional robustness tests, we include TV and newspaper advertising jointly, split our panel into two nine year periods (1995-2003 and 2004-2012), split by trading venue (NYSE/AMEX vs. NASDAQ), employ alternative measures for advertising (the logarithm of raw advertising dollars or advertising dummies) and liquidity (relative spread, price impact, and an intraday version of Amihud's illiquidity ratio), and use Fama-MacBeth (1973) instead of panel regressions for returns. Our findings remain stable.

In further tests, we analyze determinants of liquidity and show that the effect of advertising on the volume of buys is similar to the effect of advertising on the volume of sells, so that the relation between advertising and order imbalances (the key driver of price impact in the Barber and Odean (2008) model) is insignificant. We also show that volatility does not significantly increase with advertising. These results are in line with the weak relations between advertising and liquidity, as well as advertising and returns.

In summary, the stability checks show that our main results are robust: Product market advertising does not have an economically significant impact on turnover, liquidity and returns. The effect of advertising on turnover and liquidity tends to be positive, while the effect on short-term returns is virtually zero, i.e. we can not confirm the return effect documented in the literature based on yearly advertising data (e.g., Lou (2014)).

### 4.5 Reconciliation of High- and Low-Frequency Results

The results based on daily data show that there is no evidence of a causal impact of advertising on stock returns. This is in contrast to the positive contemporaneous correlation observed using yearly data of advertising and stock returns (Lou (2014); Chemmanur and Yan (2011)).<sup>23</sup> We

<sup>&</sup>lt;sup>23</sup>We note that when we aggregate our data to the yearly level, we can confirm this correlation in our sample.

hypothesize that reverse causality is an explanation for this discrepancy: Increased stock returns go along with a good economic situation of the firm and eventually more funds available for advertising. At the yearly level, it is not possible to distinguish this reverse effect from a causal effect of advertising on stock returns, because both lead to a contemporaneous positive correlation. In contrast, we can explicitly test the reverse causality hypothesis. To do so, we estimate a panel vector autoregressive (PVAR) model with stock returns and advertising as the components. We use monthly data and 12 lags, i.e., we include the entire past year in the model. In contrast to the daily level, TV and newspaper advertising are highly correlated at the monthly level ( $\rho = 0.55$ ). Thus, we use the sum of the two variables in the following analysis. We further include firm and month fixed effects to take into account cross-sectional differences between firms as well as time trends. Because we are interested in how advertising and returns change in response to one another, and returns are already price changes, we use log differences in advertising.

The impulse response functions for this model are shown in Figure 7. The panel in the upper right corner presents the effect of a one standard deviation impulse in stock returns on cumulative changes in advertising. The estimates imply that twelve months after the impulse, advertising is about 4.57 percent higher, which is significant at the 1 percent level and economically meaningful. In contrast, 12 months after an impulse to advertising, stock returns are only an insignificant 0.03 percent higher (panel in the lower left corner).<sup>24</sup>

Table D18 in Appendix D displays the coefficient estimates as well as the results from formal Granger causality tests. Columns (1) and (2) confirm that past returns have a significantly positive impact on future advertising (p-value = 0.00), while past advertising does not have a significant positive impact on future returns (p-value = 0.33). In columns (3) to (6), we rerun the PVAR model with TV and newspaper advertising separately. The estimates become more noisy, but we still find a highly significant positive impact of returns on advertising. The effect from advertising on stock returns is statistically insignificant for newspapers and economically insignificant and negative for TV advertising (less than -20bp after twelve months). Impulse response functions for TV and newspaper advertising are shown in Figures C1 and C2. Our results are also robust to using 6 or 24 lags for the PVAR components or omitting the time fixed effects.

We therefore conclude that reverse causality from stock returns to advertising likely explains the positive correlation at the yearly level documented in the literature. Since we avoid this issue by using daily data in our main analysis, this can also explain why we do not find an effect of advertising on short-term stock prices.

 $<sup>^{24}</sup>$ The impulse response functions are orthogonalized in the order advertising - stock returns, which means that the entire contemporary correlation between advertising and stock returns is ascribed to a causal impact of advertising on returns. If anything, this biases against finding reverse causality from returns to advertising. Accordingly, our results become even stronger if we reverse the orthogonalization order.

### 5 Conclusion

Using advertising to create investor attention and artificially inflate stock prices seems like a tempting opportunity for corporations and their managers. However, the findings in this paper challenge the view that stock prices can be easily manipulated by advertising. Thus, some patterns of managerial behavior like increasing advertising expenditures prior to security issuances, M&A transactions, or insider sales that are documented in the literature might have other explanations or are driven by managers wrongly believing that advertising has an impact on asset prices.

The findings in the first part of our study clearly show that advertising leads to increased investor attention as measured by the page views of the respective firm's Wikipedia page. The effect is highly significant and not driven by earnings announcements or other news events. This finding supports the idea that advertising can create investor attention and shows that advertising is a suitable proxy for non-news driven investor attention.

However, advertising creating investor attention is only a necessary condition for advertising to also affect capital market outcomes. Our further evidence shows that advertising has some impact on turnover, but the evidence for an impact on liquidity is mixed. In both cases, the economic significance of the effects is rather small.

Most importantly, we find no impact of abnormal advertising whatsoever on short-term stock returns. Our empirical setting using high frequency advertising data and firm fixed effects alleviates endogeneity concerns. Furthermore, our result are also obtained after controlling for news events like earnings announcements or newspaper articles. We try hard to find any effect by specifically looking at cases where the chances to find any potential effects on returns are best by focusing on TV channels and newspapers that are most likely be consumed by potential investors and by zooming in on firms where investor attention reacts most to advertising. However, even in these cases there is no impact of advertising on short-term returns whatsoever. While this does not preclude that there are any slow-moving investor recognition effects, these findings clearly reject the idea that advertising leads to short term attention effects that are strong enough to influence short-term stock prices.

We additionally find strong evidence of reverse causality from stock returns to advertising at the yearly level. Hence, we think that results in previous studies that find a positive relation between yearly advertising and contemporaneous returns are likely to be driven by the low data frequency and can not be interpreted as showing a causal link between advertising and returns. Thus, any attempt by managers to artificially inflate short-term stock prices via advertising seem fruitless. Why managers still seem to do so (as indicated by the results in Chemmanur and Yan (2009), Lou (2014), Hillert, Kunzmann, and Ruenzi (2015) and Fich, Starks, and Tran (2015)) is an open question.

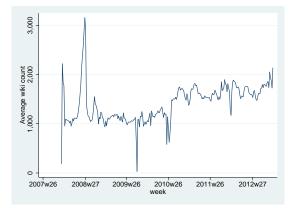

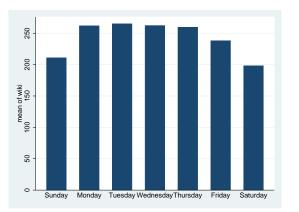

Figure 1: Average Wikipedia Page Views from 2007 to 2012

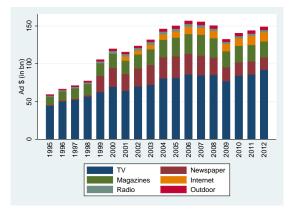

This figure displays the evolution of average Wikipedia page views per company from December 2007 - 2012. Weekly data is used to provide better readability. The increase in page views between May 17, 2008 and July 4, 2008 seems to be caused by data errors following the inclusion of other Wikimedia projects (e.g., Wikibooks.org, Wiktionary.org, etc) in the page count system. Our main results are not affected if we exclude this time period. The drop in September 2009 is due to server failures at Wikipedia over several days.

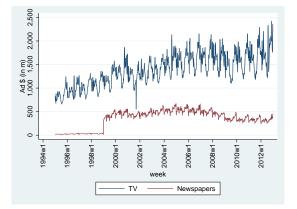

This figure displays average Wikipedia page views by day-of-the-week. The sample period is from 2007 - 2012.

This figure displays the evolution of aggregate advertising spending from 1995 - 2012. It includes all media channels for which we have data. We have daily data on TV and newspapers and monthly data on magazines, internet, radio and outdoor. The increase in newspaper advertising in 1999 is due to the start of availability for local newspaper advertising data.

This figure displays the evolution of aggregate advertising spending in TV and newspapers from 1995 - 2012. Weekly data is used to provide better readability. The increase in newspaper advertising in 1999 is due to the start of availability for local newspaper advertising data. The drop in TV advertising at the end of 2001 is due to the decrease in advertising on Sept 11, 2011 and the days thereafter.

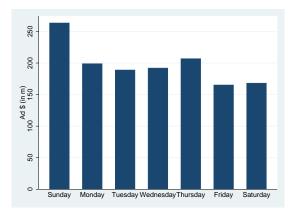

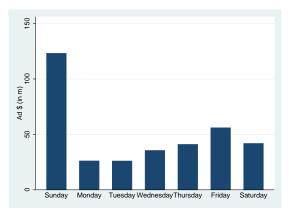

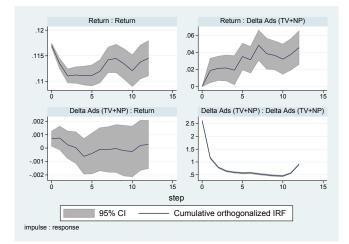

Figure 5: TV Advertising Expenditure by Day-of-the-Week

This figure displays average TV advertising dollars by day-of-the-week. The sample period is from 1995 - 2012.

This figure displays average Newspaper advertising dollars by day-of-the-week. The sample period is from 1995 - 2012.

#### Figure 7: Impulse Response Functions: Stock Returns and Total Advertising

This figure displays impulse response functions from a panel VAR model with monthly stock returns and the sum of TV and newspaper advertising as the components. For the underlying estimates see Table D18, columns (1) and (2). The impulse response functions are cumulative and orthogonalized in the order advertising - stock returns. They give the effect on the response variable for a one standard deviation shock to the impulse variable. 95 percent confidence intervals based on monte carlo simulations with 200 draws are given by the grey area around the point estimates. Delta Ads (TV+NP) are monthly log differences in the sum of TV and newspaper advertising dollars.

#### Table 1: Summary Statistics - Advertising and Investor Attention

This table gives cross-sectional summary statistics on financial market data, Wikipedia page views and Kantar advertising expenditures. The summary statistics are based on within-firm time series averages. Panel A shows statistics on all public firms. In Panel A.1, we focus on the time period from 2007 until 2012, for which investor attention data from Wikipedia is available. In Panel A.2, we focus on the time period from 1995 until 2010, for which trading data from TAQ is available. In Panel B, we present summary statistics on all firms for which Wikipedia and Kantar data is available. The time period is from 2007 until 2012. In Panel C, we present summary statistics on all firms for which TAQ and Kantar data is available. The time period is from 2007 until 2012. In Panel C, we present summary statistics on all firms for which TAQ and Kantar data is available. The time period is from 2007 until 2012. In Panel C, we present summary statistics on all firms for which TAQ and Kantar data is available. The time period is from 1995 until 2012. Wiki page views and the advertising variables are per day. MarketCap is the firm's market capitalization. Return on assets and advertising-to-sales ratios are based on Compustat data. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. News is a national newspaper article dummy. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes.

#### Table 2: Advertising and Investor Attention - Main Results

This table shows regressions of abnormal Wikipedia page visits (AWIKI) or abnormal Google search volume on abnormal advertising (AA). The sample covers all publicly listed companies with Wikipedia page visits and positive advertising in the previous 8 weeks from 2007 to 2012. AWIKI is abnormal Wikipedia page views. ASVI is abnormal Google search volume.  $AA(NP)_t$  and  $AA(TV)_t$  are abnormal advertising. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.

This table shows regressions of abnormal Wikipedia page visits (AWIKI) on abnormal advertising (AA). The sample covers all publicly listed companies with Wikipedia page visits and positive advertising in the previous 8 weeks from 2007 to 2012. AWIKI is abnormal Wikipedia page visits. AA(i)<sub>t</sub> is abnormal advertising, with i={TVNWS,TVNONWS}. TVNWS to news channels (CNN, CNBC, Fox News, MSNBC, CNN headline news), TVNONWS to all non-news TV channels All regressions include the same set of controls as in Table 2, column 5. Hence, they include Turnover<sub>t-7,t-36</sub>, Return<sub>t-7,t-36</sub>, ReaVola<sub>t-7,t-36</sub>, MarketCap<sub>t-7</sub>, AWIKI<sub>t-7</sub>. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table 4: Advertising and Investor Attention – Newspaper Subsets

This table shows regressions of abnormal Wikipedia page visits (AWIKI) on abnormal advertising (AA). The sample covers all publicly listed companies with Wikipedia page visits and positive advertising in the previous 8 weeks from 2007 to 2012. AWIKI is abnormal Wikipedia page visits.  $AA(i)_t$  is abnormal newspaper advertising, i = {NPLOC, NPNAT, NPWSJ, NP3NAT}. NPLOC refers to local newspapers, NPNAT to national newspapers (Wall Street Journal, New York Times, USA Today and Washington Post), NPWSJ to the Wall Street Journal and NP3NAT to the other three national newspapers. All regressions include the same set of controls as in Table 2, Column 5. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table 5: Impact on Financial Markets – TV Advertising

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. Turnover is daily trading volume over shares outstanding. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes. Return<sup>excess</sup> is the return of a stock over Ken French's market return. AA is abnormal advertising, defined as log-advertising-dollars today relative to log-advertising-dollars yesterday. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are shown in parentheses and clustered by firm. 1/2/3 stars denote significance at the 10/5/1%-level.

The data requirements and regression specifications are equivalent to those in the main analysis. Turnover is daily trading volume over shares outstanding. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes. Return<sup>excess</sup> is the return of a stock over Ken French's market return. For ease of presentation, only the advertising coefficients are reported. Advertising sensitivity is the firm's average coefficient for the 4 advertising-regressors in a firm-by-firm regression of AWIKI<sub>t</sub> on AA<sub>t</sub> through AA<sub>t-3</sub>, day-of-week dummies, AWIKI<sub>t-7</sub> and the usual control variables. Split is done at the cross-sectional median of advertising sensitivity. Standard errors are shown in parentheses and clustered by firm. 1/2/3 stars denote significance at the 10/5/1%-level.

# A Appendix: Variable Description

The following table briefly defines the main variables used in our empirical analysis. Abbreviations for the data sources are:

- (i) Kantar: Kantar Stradegy database
- (ii) WIKI: Wikipedia page count database
- (iii) SVI: Google SVI data
- (iv) TAQ: Trade and Quote database
- (v) CRSP: CRSP's Stocks Database
- (vi) CS: Compustat
- (vii) OP: The homepages of authors of the respective original papers

EST indicates that the variable is estimated or computed based on original variables from the respective data sources.

Variable Name	Description	Source
TV Ad \$	Daily dollar amount spent on TV advertising in 990 US TV stations, esti- mated using rate cards that give information on prices for different parts of the day and/or programs. Available from 1995 to 2012. For the analysis of investor attention (Section 3.1), we measure TV advertising for day $t$ from midnight to midnight Eastern Daylight Time, contemporaneous with our attention measure. For the analysis of financial markets (Section 4.1), we measure TV advertising for day $t$ from 4 pm (market close) on day $t - 1$ to 4 pm on day $t$ , so that evening TV ads on day t are counted towards advertising on day $t+1$ .	Kantar
News TV Ad \$	Daily dollar amount spent on TV advertising in US News TV stations. These stations are CNN, CNBC, Fox News, MSNBC and CNN headline news. Available from 1995 to 2012. For the analysis of investor attention (Section 3.1), we measure TV advertising for day $t$ from midnight to mid- night Eastern Daylight Time, contemporaneous with our attention measure. For the analysis of financial markets (Section 4.1), we measure TV adver- tising for day $t$ from 4 pm (market close) on day $t - 1$ to 4 pm on day $t$ , so that evening TV ads on day t are counted towards advertising on day t+1.	Kantar
Newspaper Ad \$	Daily dollar amount spent on newspaper advertising in 155 US newspapers, estimated using rate cards that give information on prices based on size, product categories, and days of week or sections. Available from 1995 to 2012.	Kantar
National newspa- per Ad \$	Daily dollar amount spent on newspaper advertising in four national US newspapers, namely the Wall Street Journal, New York Times, USA Today and Washington Post. Includes the Wall Street Journal and the USA Today from 1995 to 2012 and the Wall Street Journal, USA Today, New York Times and Washington Post from 1999 to 2012.	Kantar
Local newspaper Ad \$	Daily dollar amount spent on newspaper advertising in 151 local US newspapers. Available from 1999 to 2012.	Kantar
WSJ Ad \$	Daily dollar amount spent on newspaper advertising in the Wall Street Journal. Available from 1995 to 2012.	Kantar
3 National news- paper Ad \$	Daily dollar amount spent on newspaper advertising in the three other na- tional newspapers (New York Times, USA Today and Washington Post). Includes the USA Today from 1995 to 2012 and the New York Times, USA Today and Washington Post from 1999 to 2012.	Kantar

$\mathrm{AA}(\mathrm{TV})_{\mathrm{t}}$	Abnormal TV advertising on day t, defined as log-advertising-dollars on day t relative to log-advertising-dollars t-1.	Kantar, EST
$\mathrm{AA}(\mathrm{TVNWS})_{\mathrm{t}}$	Abnormal news TV advertising on day t, defined as log-advertising-dollars on day t relative to log-advertising-dollars t-1.	Kantar, EST
$\mathrm{AA}(\mathrm{TVNONWS})_{\mathrm{t}}$	Abnormal TV advertising in non-news channels on day t, defined as log- advertising-dollars on day t relative to log-advertising-dollars t-1.	Kantar, EST
$AA(NP)_t$	Abnormal newspaper advertising on day t, defined as log-advertising-dollars on day t relative to log-advertising-dollars' median of the same weekday during the last 8 weeks.	Kantar, EST
$AA(\mathrm{NPNAT})_{\mathrm{t}}$	Abnormal national newspaper advertising on day t, defined as log- advertising-dollars on day t relative to log-advertising-dollars' median of the same weekday during the last 8 weeks.	Kantar, EST
$AA(NPLOC)_t$	Abnormal local newspaper advertising on day t, defined as log-advertising- dollars on day t relative to log-advertising-dollars' median of the same week- day during the last 8 weeks.	Kantar, EST
$\rm AA(NPWSJ)_t$	Abnormal newspaper advertising in the Wall Street Journal on day t, defined as log-advertising-dollars on day t relative to log-advertising-dollars' median of the same weekday during the last 8 weeks.	Kantar, EST
AA(NP3NAT) <sub>t</sub>	Abnormal newspaper advertising in the three other national newspapers (New York Times, USA Today and Washington Post) on day t, defined as log-advertising-dollars on day t relative to log-advertising-dollars' median of the same weekday during the last 8 weeks.	Kantar, EST

Panel B: Investor attention variables						
Variable Name	Description	Source				
Wiki <sub>t</sub>	Number of times the Wikipedia page of a company was visited on day t (Eastern Daylight Time).	WIKI				
AWIKIt	Abnormal Wikipedia page views on day t, defined as log-wiki on day t relative to the log of the median of the same weekday during the last 8 weeks. The definition follows Da, Engelberg, and Gao (2011), with the only difference being that we consider daily instead of weekly data.	WIKI, EST				
$\mathrm{SVI}_{\mathrm{t}}$	Google search volume index of the company ticker on day t relative to the search volume at the first time company ticker searches were recorded in Google Trends. The data comes from Drake, Roulstone, and Thornock (2012).	SVI, OP				
ASVIt	Abnormal Google search volume index on day t, defined as log-svi on day t relative to the log of the median of the same weekday during the last 8 weeks. The definition follows Da, Engelberg, and Gao (2011), with the only difference being that we consider daily instead of weekly data. The data comes from Drake, Roulstone, and Thornock (2012). Variable Name	Description	Source	;
Turnover <sub>t</sub>	Turnover is daily trading volume over shares outstanding on day t.	CRSP,	EST
EffSprt	EffSpr is the effective spread, defined as daily transaction-weighted aver- age of transaction prices relative to prevailing quotes on day t. Specifically, $EffSpr_t = 2 P_j - Q_j /Q_j$ for each transaction, with $P_j$ being the transac- tion price, $Q_j$ the quote midpoint price, which is the average of the prevailing bid and ask quotes $(Q_j = \frac{A_j + B_j}{2})$ and $j$ is the trade. $EffSpr_t$ is then av- eraged over the day for each stock. We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, OP	EST
RelSprt	RelSpr is the relative spread, defined as daily transaction-weighted average of bid and ask quotes relative to prevailing quotes on day t. Specifically, $RelSpr_t = (A_j - B_j)/Q_j$ for each transaction, with $A_j$ being the prevailing ask quote, $B_j$ the prevailing bid quote, $Q_j$ the quote midpoint price, which is the average of the prevailing bid and ask quotes $(Q_j = \frac{A_j + B_j}{2})$ , and j is the trade. $RelSpr_t$ is then averaged over the day for each stock. We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, OP	EST,
PrcImpt	PrcImp is the price impact, defined as transaction-weighted average of 5- minute impacts on quote-midpoints on day t. Specifically, $PrcImp_t = 2 Q_{j+5} - Q_j /Q_j$ for each transaction, where $Q_{j+5}$ represents the quote midpoint price of the stock after five minutes (300 seconds), $Q_j$ is defined as above, and j is the trade. $PrcImp_t$ is then averaged over the day for each stock. We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, OP	EST,
IntAmi <sub>t</sub>	IntAmi is the intrady Amihud measure, defined as daily transaction- weighted average of the five minute price impact scaled by trade size on day t. Specifically, $IntAmi_t = 2 Q_{j+5} - Q_j /(Q_j * w_j)$ for each transaction, with $Q_{t+5}$ being the quote midpoint price of the stock after five minutes (300 seconds), $Q_j$ is defined as above, $w_j$ the transaction volume in shares, and j is the trade. $IntAmi_t$ is then averaged over the day for each stock. We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, OP	EST,

$\mathrm{Abs}(\mathrm{Return}_{\mathrm{t}})$	The absolute value of the raw return of a stock on day t.	CRSP, EST
$\mathrm{Buys}_{\mathrm{t}}$	The total traded value (in \$) of buy transactions over a day, where buy transactions are defined using the algorithm in Charles M. C. Lee (1991). We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, EST, OP
$\mathrm{Sells}_{\mathrm{t}}$	The total traded value (in \$) of sell transactions over a day, where sell transactions are defined using the algorithm in Charles M. C. Lee (1991). We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, EST, OP
OIBt	The signed difference between value of buys and sells in one day relative to the total transaction value. Specifically, $OIB_t = (Buys_t - Sells_t)/(Buys_t + Sells_t)$ , where Buys and Sells are defined as above. We would like to thank Olga Lebedeva and Stefan Obernberger for providing us with their data set. This data set has also been used in Lebedeva (2012) and Hillert, Maug, and Obernberger (2014).	TAQ, EST, OP
$\operatorname{Return_t}^{\operatorname{excess}}$	Raw excess return of a stock over the market return taken from Ken French's web page on day t.	CRSP, EST
Turnover <sub>t-7,t-36</sub>	Turnover <sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding.	CRSP, EST
$\operatorname{Return}_{t\text{-}7,t\text{-}36}$	$\operatorname{Return}_{t\text{-}7,t\text{-}36}$ is the holding period return over the 4 weeks up to t-7.	CRSP, EST
$\operatorname{ReaVola_{t-7,t-36}}$	$\rm ReaVola_{t\text{-}7,t\text{-}36}$ is realized volatility, defined as average absolute return during the 4 weeks up to t-7.	CRSP, EST
$\mathrm{MarketCap_t}$	MarketCap is the firm's market capitalization in million USD on day t.	CRSP, EST

## Panel D: Other variables

Variable Name	Description	Source
$\mathrm{News}_{\mathrm{t}}$	Dummy variable equal to one if the firm is covered in at least one of four national newspapers (Wall Street Journal, New York Times, USA Today, Washington Post) on day t. The data comes from Hillert, Jacobs, and Mueller (2014).	OP
Earnings Announcement <sub>t</sub>	Dummy variable equal to one if the firm has an earnings announcement on day t.	IBES

## **B** Appendix: Additional Information

## B.1 Wikipedia Page View Data

This section briefly describes the procedure we use to extract Wikipedia page view counts on the firm-day level.

- 1. Download of full set of page count data from December 2007 to December 2012, as provided by Wikipedia. The data can be accessed from https://dumps.wikimedia.org/other/pagecounts-raw/.This data shows the unscaled, hourly number of page views for each redirect (URL) that was used at least once in this hour to access a Wikipedia page. We have checked the precision of this data set by calling an infrequently visited Wikipedia page 10 (20) times shortly before (after) the full hour. This led to a count of 10 (20) for the Wikipedia page we called in the correct hour.
- Construction of a set of firms (permco-level) that are of interest in the context of our analysis: We use all firms available in CRSP anytime between December 2007 and December 2012 (variables used for link: name, ticker, headquarter state, time period of availability in CRSP).
- 3. Identification of firms' Wikipedia pages by searching English-language Wikipedia for the company name. If a page is found, information on ticker and headquarter state are used to make sure this actually is the Wikipedia page of the firm from CRSP. If there are separate pages for product and firm ('Coca-Cola' and 'The Coca-Cola Company'), only the firm page is used.
- 4. Manual selection of redirects that directly relate to firm name. For instance, 'Apple Computer', 'Option-Shift-K' and 'Jobs and Wozniak' all redirect to 'Apple Inc.'. We only classify the first redirect as 'directly related to firm name'.
- 5. For each hour, page counts for all redirects of each permon are added up. Then a dataset on the firm-day level is constructed by adding up hourly counts for Eastern Time (NYC) days.

## B.2 Advertising and Attention: Stability Tests

This section describes the robustness tests we conduct for our analysis of the impact of advertising on investor attention in detail. We test the robustness of our findings in Section 3.1 by looking at cross-sectional sample splits, assessing the temporal stability of the relationships, and using alternative advertising definitions. All results are presented in Table D4 in Appendix D.

In Panel A we present results based on TV advertising. In the upper left part of the panel we split the sample into firms that belong to consumer industries and firms that belong to other industries and run the same regression as in column (3) of Table 2. While we only show the impact of  $AA(TV)_t$  and  $AA(TV)_{t-1}$ , lags 2 and 3 as well as the same controls as before are included in the regression. We find highly significant coefficient estimates for both subsamples. As one might expect, the effect is somewhat stronger for firms from the consumer industry whose name might be more familiar to the viewers, but it is still substantial in nonconsumer industries, too. In the following two columns, we split the sample according to the firms' media coverage. The low (high) media coverage sample contains all firms with a below (above) median number of national newspaper articles mentioning the firm over the previous 12 months. We now find a stronger effect among firms with low media coverage. In this case, the coefficient for contemporaneous as well as lagged abnormal advertising is positive and highly statistically significant, while it is insignificant for contemporaneous AA among firms with high media coverage. The coefficient estimates are also much larger in the first case. Thus, creating attention through advertising is particularly effective for firms that are not already well-known due to their low press coverage.

In the lower left part of the panel we split our sample period into the earlier years 2007 to 2009 and the later years 2010-2012. Despite the relatively short subsample periods, we still find highly significant coefficients which are of similar magnitude as in the overall sample, confirming that our results are robust over time.

Finally, we replace our AA variables by more coarse and endogeneity-prone advertising measures. In the third column we define advertising as the natural logarithm of 1 plus the dollar amount spent on TV advertising by the respective firm, Log(1 + Ad\$). In the last column, we replace AA by a dummy variable that takes on the value one, if the firm spent at least one USD on advertising on TV on the respective day, and zero otherwise,  $I_{Ad\$>0}$ . In both cases, we still find positive coefficients of advertising on attention and the impact of contemporaneous as well lagged advertising is significant at the 1%-level.

Panel B presents the results for newspaper advertising. We find highly significant effects for firms in consumer as well as in non-consumer industries, with the coefficient estimates in consumer industries being slightly larger. Similarly, while newspaper advertising is significantly related to AWIKI for low as well as high media coverage firms, the effect is somewhat stronger for firms with low media coverage. When we split the sample into the earlier and later time period, we find significant effects in both. The same is true if we use Log(1+Ad\$) or advertising dummies.

### B.3 Advertising and Financial Markets: Stability Tests

This section describes the robustness tests we conduct for our analysis of the impact of advertising on financial markets in detail. We test the robustness of our findings in Section 4.1 by

splitting the sample based on observable firm characteristics. We also test the robustness of our results when TV and newspaper advertising are jointly included in the regression, with respect to temporal splits, splits by trading venues and the usage of other measures of advertising. The regression specifications remain the same as in Section 4.1, but in order to keep the presentation of results simple, we only report the contemporaneous and first-lag effects of advertising.

We report results for TV advertising and splits by observable firm characteristics in Table D14 in Appendix D. In the first stability check we split the TV advertising sample at the median of analyst coverage. One could expect low analyst coverage firms to be less visible to investors, so that advertising should have a particularly large effect on these firms. Indeed, the impact of TV advertising on turnover is larger for low coverage firms. It is statistically significant at the 5% (1%) level contemporaneously (at the first lag). Economic significance remains small. Again, the impact of TV advertising on illiquidity is consistently negative, but there are no clear differences between low and high coverage firms. For returns, there are not statistically significant coefficients in either group.

In the second split, we analyze low and high media coverage firms separately.<sup>25</sup> One could expect low media coverage firms to be less visible to investors and thus more susceptible to the impact of advertising. Turnover in fact seems to react more strongly to TV advertising for low coverage firms. Liquidity is impacted more for high coverage firms, while returns are unaffected for both. In any case, effects remain economically small.

In a third split by observable firm characteristics, we separately examine consumer industry firms and other firms. Consumer industry firms should be known to more retail investors, so that stronger effects of advertising could be expected for the remaining, less-known firms. Although the only statistically significant coefficients are indeed in the non-consumer industry subgroup, coefficient sizes do not systematically vary over the two groups. Signs are consistent with our previous results, i.e. TV advertising positively impacts turnover and liquidity. More importantly, the economic significance of coefficients is small for both subsamples.

In Table D15 in Appendix D, we further analyze the stability of our results. In the first test, we jointly estimate the effects of TV and newspaper<sup>26</sup> advertising.<sup>27</sup> If firms increase advertising across different channels (TV and newspapers) simultaneously, any effect measured for TV advertising might actually be due to the impact of newspaper advertising and vice versa. Correlations between AA(TV) and AA(NP) are close to zero (0.0012), so that we do not expect results to be significantly affected by this potential omitted variable bias. This is confirmed in the first stability check of Table D15 since coefficients remain similar to Table 5. TV advertising still has a positive effect on turnover, significant at the 1% level. TV ads seem

 $<sup>^{25}</sup>$ We use the number of national newspaper articles during the last 12 months in order to measure media coverage. We split at the cross-sectional median.

<sup>&</sup>lt;sup>26</sup>Results for newspaper ads are reported in Table D17 in Appendix D and discussed later in this section.

 $<sup>^{27}</sup>$ For inclusion in this panel we require a firm to have advertised at least once *on either channel* during the last 8 weeks.

to increase liquidity (statistically insignificant). Again, we observe a negative but small impact on contemporaneous returns. All effects remain economically small.

In order to analyze the temporal stability of results, we then split our sample into the 9-year subperiods of 1995-2003 and 2004-2012. The coefficient of TV advertising on turnover is higher for the pre-2003 period. This could be because during the later period algorithmic trading and the associated increase in activity may mask the relatively small impact of advertising on turnover. Liquidity on the other hand seems to be more strongly impacted by TV advertising during the post-2003 period in terms of statistical significance. Possibly, high frequency trading strengthens the effect through a quicker, more efficient detection of uninformed trading due to advertising. In both periods prices do not react to TV advertising.

Next, we split the sample by trading venue. NYSE/AMEX are limit order markets, whereas NASDAQ is a dealer market. This leads to differences in trading volumes,<sup>28</sup> and possibly in the response of financial markets to advertising-induced trading. On both types of exchanges, TV advertising impacts turnover and liquidity positively. The positive effect on liquidity seems to be stronger on NASDAQ (maybe because NASDAQ-firms tend to be less well-known), while the negative effect on stock returns is stronger on NYSE/AMEX. For both types of exchanges, the economic magnitude of effects remains low.

In a last robustness check we change our advertising measure. We believe that analyzing *abnormal* advertising-dollars is important for a clean identification: it alleviates the problem that persistent firm-specific advertising might drive our estimates. However, we find similar results when we use the log of TV advertising dollars or a dummy that indicates whether TV ads were broadcast on that day. TV advertising significantly increases turnover contemporaneously. The economic impact implied by the coefficients is comparable to our earlier results: For ln(advertising) the coefficients can be directly compared (and interpreted as elasticities), while for dummies the 0.30% increase in turnover on days with TV ads is similar in magnitude to a two to three standard deviation impact for our results based on abnormal advertising from Section 4.1. The effect of the alternative measures of advertising on liquidity is mostly positive and statistically insignificant, while the contemporaneous effect on returns tends to be negative and insignificant. Hence, the normalization of advertising does not drive our results.

Tables D16 and D17 in Appendix D describe the results of analogous stability checks for *newspaper* advertising. First, we split by firm characteristics. In contrast to our results for TV advertising, we do not find that low coverage firms are more strongly impacted by newspaper advertising. For turnover, the coefficient of newspaper advertising is actually statistically significant only in the high coverage sub group. However, overall, coefficient sizes are not systematically larger for the high coverage subgroup, particularly for liquidity and returns. Importantly, economic significance does not change markedly.

<sup>&</sup>lt;sup>28</sup>Interdealer trades on NASDAQ increase trading volumes by a factor that varies over stocks and over time, see Atkins and Dyl (1997) and Anderson and Dyl (2007).

Results for the impact of newspaper advertising in media coverage subgroups are likewise mixed. It seems that turnover for the low media coverage group reacts more strongly contemporaneously, but more weakly a day after the ad. The liquidity results indicate a higher (more positive) impact of newspaper advertising on liquidity of low media coverage firms, relative to high media coverage firms. However, coefficient sizes are economically near zero and mostly statistically insignificant. Return effects are essentially zero and insignificant.

In the consumer industry split, we find that turnover effects are larger in the non-consumer industry subgroup. Liquidity however increases in the non-consumer industry subgroup and *decreases* in the consumer industry subgroup, but coefficients are insignificant. For returns we find barely significant positive coefficients for the non-consumer industry subgroup. In any case, confidence intervals are very close to zero or include zero, i.e. effects remain economically small.

In Table D17 in Appendix D, we report the remaining stability checks. Again, jointly estimating the impact of advertising on turnover for TV and newspaper advertising does not change our results compared to Table 6.<sup>29</sup> If anything, the positive effect of newspaper advertising on turnover becomes a bit stronger when we control for TV advertising. However, it still remains economically insignificant. A doubling of newspaper advertising increases tomorrow's turnover by less than 0.1%. Liquidity and returns are not significantly impacted by newspaper advertising.

Splitting our sample into the subperiods 1995-2003 and 2004-2012, we find a stronger impact of advertising on turnover for the earlier subperiod. As discussed, this might be caused by the increased fraction of algorithmic trading in the later subperiod. The insignificance of newspaper advertising's effect on liquidity and returns is temporally stable.

In the trading venue split, we find that newspaper advertising has a slightly stronger impact on NYSE/AMEX firms' turnover. Although the statistical significance is stronger for this sub group, coefficient sizes are similar, i.e. standard errors are larger for NASDAQ-coefficients. Effects on liquidity on the other hand are stronger for the NASDAQ subgroup. Particularly the positive reaction of liquidity to newspaper advertising *yesterday* is strong and significant only for NASDAQ firms. Return effects are mostly insignificant, with the exception of a small positive contemporary impact in the NASDAQ sample.

In a last robustness check we use alternative measures of advertising. Instead of subtracting out the persistent level of newspaper advertising first, we directly use the log of advertising and a dummy that indicates whether the firm had a newspaper ad on that day. For log(advertising) we find insignificant coefficients throughout. Signs indicate a negative impact for liquidity. Importantly, confidence intervals do not include economically significant values. For the dummy specification, the effect of an ad today on tomorrow's turnover is statistically significant (10% level) and positive at +0.25%, which is in the range of the 1-2 standard deviations effect for our

 $<sup>^{29}</sup>$ For inclusion in this panel we require a firm to have advertised at least once *on either channel* during the last 8 weeks.

default abnormal advertising specification in Table 6. Other effects are insignificantly different from zero.

## C Appendix: Additional Figures

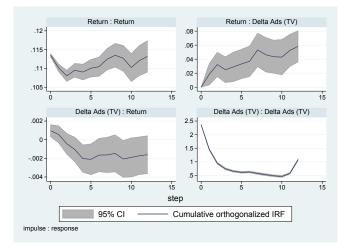

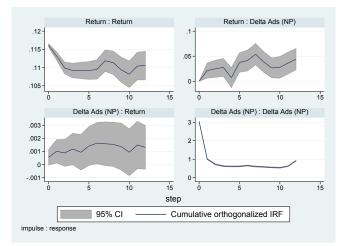

Figure C1: Impulse Response Functions: Stock Returns and TV Advertising

This figure displays impulse response functions from a panel VAR model with monthly stock returns and TV advertising as the components. For the underlying estimates see Table D18, columns (3) and (4). The impulse response functions are cumulative and orthogonalized in the order advertising - stock returns. They give the effect on the response variable for a one standard deviation shock to the impulse variable. 95 percent confidence intervals based on monte carlo simulations with 200 draws are given by the grey area around the point estimates. Delta Ads (TV) are monthly log differences in TV advertising dollars.

#### Figure C2: Impulse Response Functions: Stock Returns and Newspaper Advertising

This figure displays impulse response functions from a panel VAR model with monthly stock returns and newspaper advertising as the components. For the underlying estimates see Table D18, columns (5) and (6). The impulse response functions are cumulative and orthogonalized in the order advertising - stock returns. They give the effect on the response variable for a one standard deviation shock to the impulse variable. 95 percent confidence intervals based on monte carlo simulations with 200 draws are given by the grey area around the point estimates. Delta Ads (NP) are monthly log differences in newspaper advertising dollars.

## D Appendix: Additional Tables

#### Table D1: Summary Statistics - Advertising and Investor Attention

This table gives summary statistics on Wikipedia page visits and Kantar advertising expenditure. The sample goes from 2007 until 2012. Wiki page visits and the advertising variables are per day.  $AA(i)_t$  is abnormal newspaper advertising,  $i = \{TV, TVNWS, TVNONWS, NP, NPLOC, NPNAT, NPWSJ, NP3NAT\}$ . TV refers to all TV channels, TVNWS to news channels (CNN, CNBC, Fox News, MSNBC, CNN headline news), TVNONWS to all non-news TV channels, NP to all newspapers, NPLOC to local newspapers, NPNAT to national newspapers (Wall Street Journal, New York Times, USA Today and Washington Post), NPWSJ to the Wall Street Journal and NP3NAT to the other three national newspapers. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVolat-7,t-36 is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Panel A and B report statistics at the firm-day level on the regression samples for our TV and newspaper analyses, respectively.

	Mean	Median	SD	10%ile	90%ile	Ν

#### Table D2: Summary Statistics - Advertising and Google SVI

This table gives summary statistics on Google SVI and Kantar advertising expenditure. The sample goes from 2005 until 2008. Google search volume (SVI) and the advertising variables are per day. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Panel A to C report cross-sectional summary statistics that are based on within-firm time series averages.

#### Table D3: AR-Model Advertising

The analysis is done for 1995-2012 firm-day observations for firms with common stocks on NYSE, AMEX and NASDAQ. Advertising is daily advertising expenditure in dollars. Nontrading days are excluded, but results are stable when all days are used. Standard errors are clustered by firm. Controls are as in Table 5 and include  $EA_t$ , News<sub>t</sub>, Turnover<sub>t-7,t-36</sub>, Return<sub>t-7,t-36</sub>, ReaVola<sub>t-7,t-36</sub> and MarketCap<sub>t-7</sub>. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D4: Advertising and Investor Attention – Stability

This table shows regressions of abnormal Wikipedia page visits (AWIKI) on abnormal advertising (AA). The sample covers all publicly listed companies with Wikipedia page visits and positive advertising in the previous 8 weeks from 2007 to 2012. AWIKI is abnormal Wikipedia page visits.  $AA(TV)_t$  and  $AA_{news,t}$  are abnormal advertising. All regressions include the same set of fixed effects and controls as in Table 2, Column 5. Splits are done at the cross-sectional median except for the consumer industry split. Consumer industry is defined according to the Fama French five industry classification as in Lou (2014). Media coverage is the number of national newspaper articles on the firm in the previous 12 months. Panel A (B) displays results using television (newspaper) advertising. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.

Table D5:         Advertising and	Investor Attention – Excluding	EA and Coverage Windows

This table shows regressions of abnormal Wikipedia page visits (AWIKI) or abnormal Google search volume on abnormal advertising (AA). The sample covers all publicly listed companies with Wikipedia page visits and positive advertising in the previous 8 weeks from 2007 to 2012. We exclude days with an earnings announcement or national media coverage in the window from t-3 to t+3. AWIKI is abnormal Wikipedia page views. ASVI is abnormal Google search volume. AA(NP)<sub>t</sub> and AA(TV)<sub>t</sub> are abnormal advertising. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.

## Table D6: Summary Statistics – Advertising and Financial Markets

This table reports summary statistics on financial market data and Kantar-advertising on the firm-day level. The observations are restricted NYSE/AMEX/NASDAQ stocks, to those days when a firm's price was  $\geq 5$  last week and when it advertised at least once during the last 8 weeks, i.e. when the main data requirements for the panel regressions are fulfilled. In order to keep TAQ-based variables (available 1996-2010 only) and other variables comparable, the sample includes observations from 1996 to 2010 only. Statistics for newspaper subcategories (local papers, Wall Street Journal and the other national papers) are further restricted to the  $\geq 1999$  period, as local paper ads are available only after 1998.

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. Turnover is daily trading volume over shares outstanding. RelSpr is the relative spread, defined as daily transaction-weighted average of ask minus bid quotes relative to prevailing quote-midpoints. PrcImp is the price impact, defined as transactionweighted average of 5-minute impacts on quote-midpoints relative to prevailing quote-midpoints. IntAmi is the intraday Amihud measure, defined as transaction-weighted average of 5-minute impacts on quote-midpoints relative to prevailing quote-midpoints scaled by transaction volume (in shares). Abs(Return) is the absolute value of the raw return. AA is abnormal advertising, defined as log-advertising-dollars today relative to logadvertising-dollars yesterday. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are shown in parentheses and clustered by firm for the panel-regressions. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D9: Impact on Financial Markets – TV Advertising II

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. Turnover is daily trading volume over shares outstanding. OIB is the order imbalance, i.e. the signed difference between buys and sells in one day relative to the total transaction value. Buys (Sells) are the total traded value (in \$) in buy (sell) transactions over a day (classified according to Charles M. C. Lee (1991)). Return<sup>excess</sup> is the return of a stock over Ken French's market return. AA is abnormal advertising, defined as log-advertising-dollars today relative to log-advertising-dollars yesterday. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard-errors are shown in parentheses and clustered by firm for the panel-regressions. Fama-MacBeth regression standard-errors are Newey-West corrected (5 lags). 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D10: Impact on Financial Markets – Newspaper Advertising I

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. Turnover is daily trading volume over shares outstanding. RelSpr is the relative spread, defined as daily transaction-weighted average of ask minus bid quotes relative to prevailing quote-midpoints. PrcImp is the price impact, defined as transactionweighted average of 5-minute impacts on quote-midpoints relative to prevailing quote-midpoints. IntAmi is the intraday Amihud measure, defined as transaction-weighted average of 5-minute impacts on quote-midpoints relative to prevailing quote-midpoints scaled by transaction volume (in shares). Abs(Return) is the absolute value of the raw return. AA is abnormal advertising, defined as log-advertising-dollars today relative to log-advertisingdollars' median of the same weekday during the last 8 weeks. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are shown in parentheses and clustered by firm for the panel-regressions. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D11: Impact on Financial Markets – Newspaper Advertising II

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. Turnover is daily trading volume over shares outstanding. OIB is the order imbalance, i.e. the signed difference between buys and sells in one day relative to the total transaction value. Buys (Sells) are the total traded value (in \$) in buy (sell) transactions over a day (classified according to Charles M. C. Lee (1991)). Return<sup>excess</sup> is the return of a stock over Ken French's market return. AA is abnormal advertising, defined as log-advertising-dollars today relative to log-advertising-dollars' median of the same weekday during the last 8 weeks. EA is an earnings announcement dummy. News is a national newspaper article dummy. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are shown in parentheses and clustered by firm for the panel-regressions. Fama-MacBeth regression standard-errors are Newey-West corrected (5 lags). 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D12: Impact on Financial Markets – TV Advertising Excluding EA and Coverage Windows

The analysis is done for 1995-2012 (1996-2010) common stocks from NYSE, AMEX and NASDAQ for Turnover and Returns (TAQ-based data), excluding stocks with last-week prices below 5 USD. We exclude days with an earnings announcement or national media coverage in the window from t-3 to t+3. Turnover is daily trading volume over shares outstanding. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes. Return<sup>excess</sup> is the return of a stock over Ken French's market return. AA is abnormal advertising, defined as log-advertising-dollars today relative to log-advertising-dollars yesterday. Turnover<sub>t-7,t-36</sub> is the trading volume over the 4 weeks up to t-7, divided by average shares outstanding. Return<sub>t-7,t-36</sub> is the holding period return over the 4 weeks up to t-7. ReaVola<sub>t-7,t-36</sub> is realized volatility, defined as average absolute return during the 4 weeks up to t-7. MarketCap is the firm's market capitalization. Standard errors are shown in parentheses and clustered by firm for the panel-regressions. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D14: Impact on Financial Markets – TV Advertising Robustness I

The data requirements and regression specifications are equivalent to those in the main analysis. Turnover is daily trading volume over shares outstanding. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes. Return<sup>excess</sup> is the return of a stock over Ken French's market return. For ease of presentation, only the contemporary and first lag effects of advertising expenditures are reported. Splits are done at the cross-sectional median except for the consumer industry split. Consumer industry is defined according to the Fama French five industry classification as in Lou (2014). Media coverage is the number of national newspaper articles on the firm in the previous 12 months. Standard errors are clustered by firm for the panel-regressions. 1/2/3 stars denote significance at the 10/5/1%-level.

Table D17: Impact on Financial Markets – Newspaper Advertising Robu
---

The data requirements and regression specifications are equivalent to those in the main analysis. Turnover is daily trading volume over shares outstanding. EffSpr is the effective spread, defined as daily transaction-weighted average of transaction prices relative to prevailing quotes. Return<sup>excess</sup> is the return of a stock over Ken French's market return. For ease of presentation, only the contemporary and first lag effects of advertising expenditures are reported. Standard errors are clustered by firm for the panel-regressions. 1/2/3 stars denote significance at the 10/5/1%-level.

#### Table D18: Panel VAR with stock returns and advertising

This table reports the results of panel VAR models with monthly stock returns and different measures of advertising as the components. The measure of advertising is  $\Delta$  Ads (TV+NP), which is the log difference of the sum of TV and newspaper advertising, in VAR1,  $\Delta$  Ads (TV), which is the log difference of TV advertising, in VAR2, and  $\Delta$  Ads (NP), which is the log difference of newspaper advertising, in VAR3. The analysis is done for 1995-2012 common stocks from NYSE, AMEX and NASDAQ, excluding stocks with prices below 5 USD in the month before the estimation period and those with no advertising in the two months before the estimation period. The model is estimated following the extension of standard vector autoregression to the panel context by Holtz-Eakin, Newey, and Rosen (1988) and using the program developed by Love and Zicchino (2006) and Abrigo and Love (2015). It takes firm fixed effects into account by forward orthogonal deviations and month fixed effects by monthly demeaning the variables. The  $\chi^2$  statistics and associated p-values are for the granger causality test that all lags of a variable are jointly zero. The tests have twelve degrees of freedom. Standard errors are clustered by firm and shown in parentheses. 1/2/3 stars denote significance at the 10/5/1%-level.
