

CEO Innate Altruism and Firm Corporate Social Responsibility

Miriam Marra, Jing Ruan, Lisa Schopohl,* Chao Yin**

We examine the impact of CEO's innate altruism on firm corporate social responsibility performance (CSR). We measure CEOs' innate altruism using the Global Preference Survey scores associated with the CEOs' ancestral countries of origins. Firms led by more altruistic CEOs have stronger CSR performance after controlling for firm financial and corporate governance attributes and other CEOs' characteristics. The result survives several robustness and endogeneity checks, including propensity score matching and difference-in-difference regressions around exogenous CEO turnover events. The link between CEO altruism and CSR is stronger in well-governed firms and CEO innate altruism is not value-destroying for shareholders.

CEO Innate Altruism and Firm Corporate Social Responsibility

1. Introduction

Corporate Social Responsibility (CSR) has become increasingly important over the last two decades with more firms adopting CSR policies, increasing their spending on social and environmental initiatives and reporting on their CSR performance to their shareholders and the general public. CSR typically refers to the activities that organizations carry out to protect and improve society's wellbeing and the physical environment, beyond the direct economic and technical interests of the firm and what is imposed by legislative norms (McWilliams and Siegel, 2000, 2001; Waddock, 2004; Waldman, Siegel and Javidan, 2006; Kitzmueller and Shimshack, 2012). These CSR initiatives span a variety of issues from firms' internal corporate policies around employee relations and workforce diversity, to their external institutional engagement and impact via community relations, environmental impact, and human rights considerations.

Despite the increasing popularity of CSR, there is a considerable variation in the CSR performance among firms, with some companies championing CSR and others not engaging in any form of CSR activities beyond legal requirements.¹ In this paper, we explore the variation in firms' CSR performance by studying the role of the CEO's cultural heritage. In particular, we look at the impact that the CEO's innate altruism has on the firm's overall CSR performance.

Altruism can be defined as "unselfish regard for or devotion to the welfare of others" (Merriam-Webster dictionary, 2022). Fehr and Fischbacher (2003) provide an economic and behavioral definition of altruism as "costly acts that confer economic benefits on other individuals".

CSR, by definition, signals policies and corporate activities that are – at least partially – *altruistic* (other-considering), as it captures corporate social or environmental behaviour that goes beyond any legal or regulatory requirements and benefits the interests of a broader stakeholder base beyond firms' shareholders. CSR also conveys the message that the corporate leadership considers the impact of their decisions upon the social good and broad stakeholder interest in the expectation that this will flow back as "positive attribution or moral capital" (Godfrey et al., 2009). As the CEO is the main corporate decision-maker and responsible for setting the corporate strategy, his/her preferences and innate values are expected to play a crucial role in firms' CSR performance.² Hence, we argue that

¹ In our sample, we observe a dispersed distribution of CSR performance. Our overall adjusted CSR score has a mean of 0.156, a standard deviation of 0.690, and a value range of 6.311.

² Previous research has shown that individual CEOs and their personal characteristics have much stronger explanatory power for the firm's CSR performance than firm-specific factors (see, for instance, Davidson et al., 2019).

firms led by CEOs that have stronger altruistic tendencies will engage more in altruistic policies and activities and will therefore show a better CSR performance than firms led by less altruistic CEOs. Building on the literature that highlights the importance of cultural heritage in shaping individuals' beliefs and values (e.g., Giavazzi, Petkov, and Schiantarelli, 2014; Dohmen, Falk, Huffman, and Sunde, 2012; Becker, Dohmen, Enke, and Falk, 2020; Pan, Siegel, and Wang, 2020, Nguyen, Hagendorff, and Eshraghi, 2018), we measure a CEO's innate altruism by looking at the level of altruism attributed to his or her ancestral country of origin, using the preference scores from the Global Preference Survey associated with that country. The CEOs' ancestral countries of origin are the countries from where their ancestors came from when migrating to the U.S. We infer those origins from the CEOs' surnames and the U.S. immigration passengers' records retrieved from the Ancestry.com website. Each CEO's surname is associated to one country for which the surname appears with the highest frequency in the immigration records. The U.S. is a multicultural society with a long immigration history, so it provides substantial variation in cultural origins. In the U.S., most people tend to marry within their ethnic group (endogamy); thus, the society appears more like a 'salad bowl' than a 'melting pot' (Bisin and Verdier, 2000; Kalmijn, 1998): many individuals tend to continue referring – to various extent - to the values embedded in their cultural heritage. Therefore, the U.S. provides an interesting case-study to understand the influence of cultural origins in corporate decision-making. Another merit of our research design is that a single-country study enables to keep the corporate culture and the institutional environment constant and let only cultural heritage vary across CEOs, with the clear advantage of singling out other country-level confounding factors (such as the level of economic, social, political development, and relevant institutional features).

Using multivariate panel regression analysis with firm and year fixed effects, we are able to show that firms led by more altruistic CEOs have higher ratings in overall CSR performance after controlling for many firm attributes (financials and corporate governance controls) and for CEOs' other ethnically-inherited cultural values and individual characteristics (such as age, gender, and tenure). The results remain robust to a battery of robustness checks and endogeneity tests, including propensity score matching and difference-in-difference regressions used as quasi-natural experiment based on changes in CEO altruism following exogenous CEO turnover events.

We further explore what might be driving the link between CEO's innate altruism and firm's increased CSR performance. In the corporate finance literature, there are two opposing views regarding the drivers of CSR (see Ferrell, Liang, and Renneboog, 2016): the 'agency view' which regards CSR as a manifestation of agency conflicts between firm management and shareholders and,

as such, a mis-use of corporate resources (see Friedman, 1970; and further explored in Benabou and Tirole, 2010; Masulis and Reza, 2015), and the ‘good governance view’ of CSR which understands CSR as a consequence of good corporate governance by incorporating the views of firms’ broader stakeholder base, which can be value maximising (see Freeman, 1984; and further explored in Edmans, 2011; Deng, Kang, and Low, 2013). We find that the link between CEO altruism and CSR is stronger in well-governed firms where the CEO is not overly powerful. In addition, firms with more altruistic CEOs do not show worse financial performance, suggesting that altruism, as an innate trait of CEOs, is not value-destroying for shareholders. Instead, we find evidence that suggests that CEO altruism may shield the firm from financial under-performance during a crisis period and so it may benefit shareholders at those times.

Our paper makes several contributions to the literature. Firstly, we contribute to the literature that investigates the importance of CEO personal characteristics in explaining firms’ CSR policies and performance. Previous studies have shown for instance that CEO confidence (McCarthy, Oliver, and Song, 2017), CEO ability (Yuan et al., 2019), CEOs’ degree of narcissism (Al-Shammari, Rasheed, and Al-Shammari, 2019), their political affiliation (Chin, Hambrick and Treviño, 2013), whether they have a daughter (Cronqvist and Yu, 2017) and their ownership of materialistic goods (Davidson et al., 2019) affect the CSR performance of the companies that they lead. We add to this literature by demonstrating that CEOs’ cultural heritage and in particular their innate altruism serves to explain their firms’ CSR.

Secondly, our study provides novel insights to the stream of literature that explores the role of managers’ cultural heritage on their corporate decision-making. It has been shown by prior studies that a variety of values and personal traits rooted in managers’ cultural heritage affect their firms’ policies and decisions, such as CEOs’ ancestral uncertainty avoidance in the context of mergers and acquisitions (Pan et al., 2020), their innate level of trust and individualism as a determinant of corporate innovation (Nguyen, 2019; Gao et al., 2021), and CEOs’ ancestral degree of restraint, group-mindedness, uncertainty avoidance and long-term orientation in the context of cost efficiency efforts and corporate acquisitiveness (Nguyen et al., 2018). However, to the best of our knowledge, no previous study has explored the role of CEOs’ cultural heritage on their propensity to improve their firms’ CSR performance, and in particular the role of CEO’s innate altruism in driving the allocation of corporate resources.

Finally, we add to the vast body of research that investigates whether CSR is driven by agency conflicts between managers and shareholders or rather signifies an expression of good corporate

governance. The existing literature provides conflicting findings with some studies supporting the CSR agency view (e.g., Benabou and Tirole, 2010; Masulis and Reza, 2015; Ferrell et al., 2016) and others providing evidence in line with the good governance view of CSR (e.g., Edmans, 2011; Deng et al., 2013; Davidson, Dey, and Smith, 2019; Liu, Hou, and Main, 2022). While both views are not necessarily mutually exclusive and different CSR activities may be driven by different motives, our findings of the positive link between CEO altruism and CSR are more in line with the good governance perspective of CSR.

The rest of the paper is structured as follows. Section 2 reviews the relevant literature and develops the hypothesis. Section 3 presents the data and empirical methodology. Section 4 illustrates the main results of our panel regressions and presents numerous robustness and endogeneity checks. Section 5 investigates the agency view versus the good governance view of CSR, while Section 6 summarises the conclusions of our study.

2. Literature review and hypothesis development

2.1 Cultural transmission

Our study builds on the literature on transmitted cultural values that highlights the role of cultural origins in shaping individuals' cultural traits. Guiso, Sapienza, and Zingales (2006) show that the heritage culture is a persistent trait: the beliefs and values that ethnic groups transmit remain fairly unchanged from generation to generation. They compare the World Value Survey (WVS) with the U.S. General Social Survey (GSS), which inquires about participants' ethnic origin. The U.S. data show a strong effect of ethnic origin on the current set of values. For example, there is a significant positive correlation (0.6) between the trust level of U.S. immigrants from different countries and the trust level of nationals in the corresponding U.S. immigrants' countries of origin. Similarly, Tabellini (2008) shows that trust attitudes of third-generation U.S. immigrants, who have had time to adapt to their new environment, can still be explained by the political institutions and education prevailing around or before 1900 in the ancestors' countries of origin. These findings are consistent with the idea that individual beliefs have a cultural heritage component, which is transported to the 'new' environment and continues to impact them even a few generations later. While it is beyond the scope of our study to investigate this matter in detail, there are a few explanations about why cultural heritage is transmitted from one generation to the next. For instance, one explanation is that parents evaluate their children's actions with their own preferences and therefore attempt to shape them based on their

own cultural traits (Bisin and Verdier, 2000, 2001). This also helps to explain the marital segregation in the U.S. because endogamy is more efficient in terms of cultural transmission: according to the U.S. Census Bureau the vast majority (90%) of married-couple households across all States are not interracial or interethnic.³

Some empirical evidence has been provided on the causal effect of inherited beliefs on various economic outcomes. For instance, Algan and Cahuc (2010) estimate the inherited component of trust for U.S. immigrants and show that it is significantly influenced by their country of origin has a significant impact on economic growth. Ellahie et al. (2017) use the ethnicity of CEOs as a proxy for their common inherited beliefs and values and document a strong (fixed) effect of ethnicity in the variable proportion of CEO compensation. Liu (2016) derives a corporate corruption measure from the corruption levels in the corporate insiders' countries of ancestry and shows that firms with higher corruption culture tend to be more tolerant toward corrupt behaviour and are more likely to engage in corporate misconduct. Nguyen et al. (2018) show that banks led by CEOs whose ancestral origins emphasize restraint, group-mindedness, uncertainty avoidance and long-term orientation are more cost-efficient and more cautious with acquisitions, which, in turn, explains their outperformance under competitive pressure. Pan et al. (2020) find that U.S. firms managed by CEOs with origins in cultures with higher uncertainty avoidance are significantly less likely to engage in acquisitions. Nguyen (2019) looks at the variation in the cultural origin's trust level across CEOs and between CEOs and firm's innovators (researchers) to explain firms' and inventors' patenting and impact on corporate innovation. Collectively, these findings highlight the importance of a CEO's *intrinsic* characteristics and cultural heritage on key corporate strategies. However, none of the reviewed study focuses on CSR and on CEOs' innate altruism.

2.2 CEO characteristics and CSR

Several studies document interesting correlations between a firm's CSR characteristics and various demographic and/or individual traits of the CEO (Huang, 2013; Borghesi, Houston, and Naranjo, 2014). Demographics are, in many cases, used to proxy for the underlying values of an individual because, as Hambrick and Mason (1984) argue, they help to examine values and cognitive biases of individuals. For instance, existing studies document that female CEOs, CEOs with certain bachelor's and advanced degrees, younger CEOs, CEOs who have at least one daughter, and those

³ Data related to the years 2012-2016 retrieved from <https://www.census.gov/library/stories/2018/07/interracial-marriages.html> (last accessed on 24 November 2022).

who make political contributions are more likely to make CSR investments (see Godos-Díez, Fernandez-Gago, and Martínez-Campillo, 2011; Papagiannakis and Lioukas, 2012; Cronqvist and Yu, 2017). Davidson et al. (2019) find that firms led by materialistic CEOs have lower CSR scores, fewer CSR strengths, and more CSR weaknesses, measuring CEOs' materialism with their ownership of vehicles, boats, and real estate. McCarthy, Oliver, and Song (2016) show that more confident CEOs underestimate firm risks, which, in turn, leads them to undertake relatively less hedging and performing less CSR activities. Petrenko et al. (2016) report that narcissistic CEOs⁴ are more invested in socially responsible initiatives because they want to draw attention to themselves and achieve their need for acclaim and fame. Al-Shammari, Rasheed, and Al-Shammari (2019) find that while CEO narcissism is positively related to externally oriented CSR, the relationship between CEO narcissism and internally oriented CSR is negative but not significant.

The paper by Guo, Kong, and Zhang (2018) is the closest to our study: they find that firms managed by CEOs who make regular charitable donations have significantly higher CSR performance than those managed by CEOs who only occasionally donate or never donate. Their finding suggests that CEOs' socially-responsible behaviours on a personal level can then translate into corporate socially-responsible behaviours. It is challenging to measure quantitatively the individual CEO's preference for altruism. Looking at CEOs' personal donations can be one way as donations fulfil the psychological value of altruism. However, corporate donations can also be driven by politics, lobbying, tax avoidance reasons and support for the so-called CEO 'pet projects' (Yermack, 2009). We connect altruism to the CEOs' cultural heritage instead. Although our country-level innate altruism measure is not directly related to the CEO's individual behaviour and choices, it should not be impacted by an opportunistic rationale that can cause measurement errors and misspecifications.

2.3 Hypothesis development

The upper echelons theory suggests that organizational outcomes are partially predicted by the background characteristics of the top-level management team. As a result, the strategic choices CEOs make, included those related to CSR policies, can be explained by their characteristics, personal traits, and their own 'lenses' (Hambrick, 2007; Hambrick and Mason, 1984). CEOs are broadly believed to affect, in some manner, firm outcomes due to their involvement in establishing a firm's culture and providing leadership (Berson, Oreg, and Dvir, 2008).

⁴ CEO narcissism is a measure based on the prominence of the CEO's photograph in the company's annual reports and appearance in press releases, and on the CEO cash and non-cash compensation.

Culture has received growing attention in the finance literature in recent years. It can be defined as “the collective programming of the mind that distinguishes members of one country from another” (Hofstede, 1984, 2001; Hofstede et al., 2005) and serves as a mechanism that shapes individuals’ values and preferences. Hence, CEOs’ cultural heritage can have a significant role in shaping their beliefs, behaviours, and choices, not just at a personal level but also for the firms they lead.

Although culture is a multi-dimensional concept, altruism is particularly relevant to a firm’s CSR performance. Because altruism represents a focus on others rather than self, potentially resulting in self-sacrifice, altruistic CEOs are less likely to take actions only targeted to maximize their compensation (Zajac and Westphal, 1995) – typically aligned to shareholders’ interests - and are more likely to consider the effect of firm actions on the firms’ multiple stakeholders, including employees, customers, and other societal members, as emphasized by the stakeholder approach (Harrison and Freeman, 1999).

The perceived altruistic behaviors of top management teams and particularly CEOs who may have the greatest discretion to direct the corporation in accordance with their own altruistic preferences could be reflected in the expected benefits to the firm from socially responsible investments (Borghesi, Houston, and Naranjo, 2014; Waldman, Siegel, and Javidan, 2006).

This is consistent with the findings of prior research that suggested links between altruism and willingness to contribute to public goods (Andreoni, 1990; Clark, Kotchen, and Moore, 2003), including actions that are beneficial to maintaining the physical environment. For example, while a greedy CEO may be more prone to “taking shortcuts,” such as investing less in environmental clean-ups, polluting more,⁵ or reducing the investment in quality customer service or product control to achieve the short-term performance goals, we expect altruistic CEOs to be more inclined to undertake environmentally friendly actions, such as reducing carbon emissions or other forms of pollution. The altruistic CEO may also focus on the welfare of those within the company. She or he may be less aggressive in negotiations, for instance, providing more concessions in labour negotiations, such as more generous employee benefits. In addition, altruistic CEOs may seek to improve the quality of the workplace on behalf of employees. The altruistic CEO’s focus on others is likely to create goodwill that benefits the firm in the long run. A high level of mutual altruism may also reduce agency problems

⁵ In the accusation against BP following the Macando well explosion that resulted in an estimated four-million-barrel oil spill in the Gulf of Mexico in 2010 the Alabama’s attorney general during the civil trial stated that “BP was blinded by greed . . . Greed devastated the gulf”.

within and outside a firm. Altruistic CEOs are often concerned for the well-being of multiple stakeholders of the firm (as opposed to only those of shareholders). For instance, an altruistic CEO may be less willing to pursue cost savings that require the closing of facilities, elimination of jobs, or offshoring of positions, out of concern for those who would be affected.

In this study, we look at the relationship between the innate altruism of the CEO and the firm's CSR performance by following an "epidemiological approach" (Fernández, 2011) as we separate innate culture from the local environment and study the decision-making outcomes of individuals (the CEOs) with potentially different cultural backgrounds within a common economic and institutional setting. We test the following hypothesis:

Hypothesis: CEOs whose ancestral countries of origin have a higher score of altruism are more likely to engage with and perform better in CSR.

3. Data

3.1 Measuring cultural origin and dimensions

Since self-reported data on CEO cultural origin are not available, we follow Pan et al. (2020) and infer CEOs' cultural origins from their surnames using the passenger lists of ships arriving at the port of New York from 1820-1957, available at the website Ancestry.com. The passenger lists provide passengers' first names and surnames (family names), date of arrival, ethnicity, and other demographic characteristics. We search for each CEO's surname and use the ethnicity of passengers with the same surname to estimate the frequency distribution across ethnicity. We then attribute to each surname the country with the highest frequency for that specific surname: this country will be inferred as the country of origin of the CEO. For female CEOs, we use their maiden names to infer their culture of origin. We identify maiden names from various sources, including Marquis Who's Who, NNDB.com, and Google searches.⁶ In summary, we create a dataset where we map CEOs' surnames to ethnicity data from passenger records to countries of origin and then to the country-level culture dimensions, and more specifically to the altruism score.⁷ Our surnames dataset contains information about the

⁶ In few cases, we are unable to identify a female CEO's maiden name. Notably, female CEOs only accounts for 3% of our sample. Also, the culture and values of individuals are surely affected also by their mothers' cultures. We cannot retrieve information about the surnames of CEO's mothers. However, we think that both these information gaps (female CEO's maiden names and CEOs' mother surnames) may not be serious issues in the U.S. context: intra-ethnic marriage rates are quite high in the U.S., as mentioned in section 1.

⁷ Note: we map English, Welsh and Scottish to Great Britain. In a few cases, the ethnicity can only be ambiguously associated with *one* country of origin. For example, 'Scandinavian' is reported in the records as a uniform group. When a surname is ambiguously associated to Scandinavia, we look at the Scandinavian country where the surname reports the highest frequency and use that country (Denmark, Norway, or Sweden). We drop those records where the information

ethnicity in passenger records for 4,581 different surnames which are linked to 5,934 different U.S. CEOs.⁸

We obtain the culture scores from the Global Preference Survey, which relies on a range of qualitative and quantitative survey items to construct preference measures from 80,000 people in 76 countries (Falk et al., 2018). This empirically-validated survey captures preferences across countries in the following dimensions: time preference, risk preference, positive and negative reciprocity, altruism, and trust. Altruism is constructed using a qualitative and a quantitative question, both related to donations. The qualitative question asks respondents their willingness to give to a charitable cause without expecting anything in return. The quantitative scenario describes a situation where the respondent receives 1,000 euros unexpectedly and is asked to indicate how much they would donate.

While the surname approach is widely used in the finance literature to identify cultural origins (e.g. Hegde and Tumlinson, 2014; Liu, 2016), one concern is that its use to infer the country of origin may still involve some measurement error (Giannetti and Zhao, 2018). First, Pan et al. (2020) perform a cross-validation with data from Nguyen et al. (2018), as the two papers use slightly different surname-ethnicity identification approaches. Both approaches yield the same origin in 80% of cases and most mismatches are close to one another. Second, in this study we provide results using an alternative measure of cultural heritage. We create an alternative altruism score as the weighted average of the altruism associated with each country-of-origin j : $Altrusim_l = \sum w_{lj} \times Altruism_j$, where the w_{lj} is the frequency of surname l in country j that appears in the passengers' records. We discuss the results of this alternative measure in the robustness checks section 4.3.

3.2 Sample construction

Following a large body of finance studies related to firm's CSR choices (e.g. Jiao, 2010; El et al., 2011; Jo and Harjoto, 2012, and McCarthy et al., 2017), we use the ratings provided by Kinder, Lydenberg, and Domini (KLD) Stats to construct our measure of CSR performance. KLD provides the most comprehensive data on firm's social performance assessed across seven major categories: community (COM), workforce diversity (DIV), employee relations (EMP), human rights (HUM), environment impact (ENV), product quality and corporate governance. In this study, we use the KLD ratings for five categories, which are the aforementioned seven categories excluding product quality and corporate governance. Following previous literature (see, for instance, Hong and Kostovetsky,

on ethnicity is missing or unidentifiable. Passenger records in which the ethnicity is reported as American are also excluded because they identify returning U.S. citizens.

⁸ We are able to identify a dominant country of origin for around 90% of the CEOs.

2012; Servaes and Tamayo, 2013, Lins, Servaes and Tamayo, 2017), we do not include product quality and corporate governance as they cover a number of items that we consider to be outside the scope of CSR.⁹ Our KLD sample period covers 1992 to 2018.

For each individual category, KLD assigns a binary score (0/1) to a set of strengths and concerns. Each strength or concern is assigned a value of one if it meets the specified criteria, and a value of zero otherwise. Some studies use ‘raw’ CSR scores obtained by subtracting the number of concerns from the number of strengths for each CSR category and aggregate them to form an overall CSR score. However, this could lead to a biased measurement because the number of CSR items varies across years and the number of strengths and concerns items varies across categories. Therefore, we follow Deng et al. (2013), Servaes and Tamayo (2013), and Lins et al. (2017) and construct an adjusted CSR score. We first calculate the total strength (concern) score for each category and then divide it by the maximum number of strengths (concerns) for each category to obtain the adjusted strength (concern) scores for that category. Then we capture the performance of a firm for each category of CSR by subtracting the adjusted concern score from the adjusted strength score. Finally, the overall adjusted CSR score is the sum of all adjusted CSR category scores. Hence, the possible range of the overall adjusted CSR score is -5 to +5.

We also collect a large number of variables intended to be used as controls in regression analysis: they are time-varying firm characteristics and CEO-specific variables that capture their demographic features and their external incentives. We construct this sample of variables from several different sources. We start from ExecuComp, which provides executive names and CEO-related information for S&P 1500 firms starting from 1992. During years of CEO turnover or in the few cases where the firm has a co-CEO, we assign to the firm the CEO with the CEO annual flag (CEOANN) in the specific fiscal year, which in turn is based on who was identified as the CEO in the firm’s summary compensation table. From ExecuComp we also collect information on CEO’s age, gender, and tenure. Prior research find that firms led by female CEO are more likely to engage in socially responsible corporate practices (e.g., Manner, 2010; Kimball, Palmer and Marquis, 2012; Matsa and Miller, 2013). CEO age is observed to have both a direct influence (Fabrizi, Mallin, and Michelon, 2014; Oh, Chang, and Cheng, 2016) and a moderating role (Meier and Schier, 2021) on CSR. Chen, Zhou, and Zhu (2019) find that firms’ CSR performance decreases with the CEO tenure.

⁹ However, our results continue to hold when we include the product category in the overall CSR score.

Next, to obtain information on CEO/chairman duality (i.e., whether the chairman of the board and CEO are the same individual), we merge the ExecuComp sample with BoardEx using the ISIN number as common firms' identifier across the two datasets. For each firm, we then match executives reported in BoardEx with the CEOs reported in ExecuComp by calculating the Levenshtein distance between executive names and hand-checking the CEO-name match when necessary.¹⁰

Firms' financial information is retrieved from Compustat. As larger and more profitable firms may have greater resources for CSR expenditures (Wu, 2006; Campbell, 2007), we collect information on firm profitability and firm size, proxied by return on assets (measured as earnings before interest and taxes to total assets) and natural log of total assets respectively. Firms with lower risk are generally more likely to engage in CSR activities (Orlitzky and Benjamin, 2001), thus we also include leverage measured as long-term debt plus debt in current liabilities divided by total assets. We consider R&D expenditures (scaled by total assets) as firms with higher R&D expenditures appear to invest more heavily in CSR (McWilliams and Siegel, 2000). Furthermore, we include free cash flow defined as cash flow from operations minus capital expenditures because firms with more cash can afford to conduct more CSR activities (Lys et al., 2015).

Finally, we add to this dataset the firm's institutional ownership data from the Refinitiv database because institutional investors' monitoring attention and selective preferences could influence the CSR policies of their portfolio of firms (Nofsinger, Sulaeman and Varma, 2019; Chen, Dong, and Lin, 2020). The data on the percentage of shares held by different types of investors start in 1997, therefore our final merged sample starts from 1997 and ends when KLD data ends in 2018.

Financial and utility firms are excluded from the sample. Continuous variables are winsorized at 1% and 99%. Our final sample consists of 7,823 firm-year observations for 992 U.S. firms with 1,704 CEOs, whose ancestral origins are traced back to 29 different countries.¹¹ Table A2 in Appendix illustrates the frequency of the countries of origin in our sample.

3.3 Summary statistics

Table 1 presents the descriptive statistics of all variables used in our main tests, including CSR ratings, culture scores, and firm and CEO characteristics. All variable definitions and sources are listed in Table A1 in the Appendix.

¹⁰ We keep all matches that have a Levenshtein distance below 10. If the matching is not one to one, we manually checked by comparing executive's name, role, and start/end date.

¹¹ Our final sample size is comparable to recent studies that use ExecuComp and KLD database, e.g. McCarthy, Oliver and Song, 2017; Chen, Zhou and Zhu, 2019.

The overall adjusted CSR score ranges from -1.867 to $+4.444$, and its sample mean is 0.156 . The mean CSR score is positive for each of the five primary categories, which indicates that, on average, firms in our sample have more strengths than concerns.

Our variable of interest, CEO altruism, has a mean of -0.013 and a standard deviation of 0.191 , which is close to the distribution described in the Global Preference Survey. GPS integrates the quantitative and qualitative questions associated with altruism into a single score for each surveyed individual. The score is standardized to have a mean of zero and standard deviation of one at the individual level. 12.3% of the variation in the individual level is then attributed to cross-country differences in preference for altruism (Falk et al., 2018).

With respect to firm and CEO variables, the average firm size is 9.5 billion dollars; the average ROA is 11.5%; the average leverage is a little less than 20% on a book value basis; and the free cash flow is 763.5 million dollars. On average, firms spend 4.6% on R&D and the percentage of shares held by institutions is 81.4%. The majority of CEOs in the sample are male, while only 3.1% of the firm-year observations are associated to female CEOs. The average CEO age is 56 years, and the average tenure is around 8.1 years. The descriptive statistics for firm and CEO characteristics in our sample closely resemble those of other studies that also focus on large U.S. public firms over a similar sample period (e.g., Cronqvist and Yu, 2017; Yuan et al., 2019; Chen, Dong, and Lin, 2020).

[Insert Table 1 here]

4. Empirical Analysis

4.1 Main methodology

We start by estimating the following baseline multivariate panel regression with CEO and firm controls and a set of fixed effects (i represents the firm, t the year). CEO Altruism is the key regressor and it is the innate measure of CEO altruism derived from the GPS altruism score associated to the CEO's country of origin.

$$\begin{aligned}
 CSR\ Score_{it} = & \alpha_1 + \beta_1 CEO\ Altruism_{it} + \beta_2 CEO\ Age_{it} + \beta_3 CEO\ Gender_{it} \\
 & + \beta_4 CEO\ Tenure_{it} + \beta_5 Firm\ Size_{it} + \beta_6 ROA_{it} + \beta_7 Leverage_{it} \\

 \end{aligned} \tag{1}$$

We alternate this specification with one that also include industry fixed effects in lieu of firm fixed effects. Estimated standard errors are clustered at the firm level.¹²

4.2 Baseline Regression Results

Table 2 reports the results of our baseline panel regression analysis. In all regression specifications the CEO's country of origin altruism score results in a higher KLD CSR score for the firm led by the specific CEO. As shown, the coefficient on the CEO altruism, ranging from 0.181 to 0.292, is consistently positive and statistically significant at the 1% level across the model specifications (for the specification in column 2 significance is at the 5% level).

The panel regressions in columns (1) and (2) include year and firm fixed effects. We observe a positive and statistically significant impact of CEO's altruism on the overall CSR score. For example, column (1) suggests that when a CEO's innate altruism score increases by one standard deviation, the firm's CSR rating will increase on average by 0.043 (0.224×0.191), *ceteris paribus*. This translates into an approximately 27.6% ($0.043/0.156$) increase in the firm's CSR rating, compared to a firm that takes an average value in our sample. The effect is therefore both economically and statistically significant (at the 1% level).

In the specifications of columns (3) and (4) the panel regressions include year and industry fixed effects (using the two-digit SIC industry classification) to account for systematic unobservable variations in the dependent variables across year and industry. The result that CEO innate altruism positively impacts the firm's CSR score remains unchanged. In the third column, we find that the coefficient of altruism is positive (0.193) and statistically significant at the 1% level (t-statistics of 3.075). Interestingly, in columns (2) and (4) we control for all other country-of-origin cultural dimensions included in the GPS (patience, risk taking, positive and negative reciprocity, trust) and find that none of them is statistically significant; only altruism appears to be strongly related to the CSR score.¹³

¹² In unreported checks we use all other possible clustering methodologies (at industry level, year level and industry-year level) and our results remain unchanged. In addition, as explained in section 4.3, we run the regression with all dependent variables lagged by one year and results do not vary.

¹³ The altruism score has about 8% correlation with patience, 24% with risk, 83% with positive reciprocity, -3% with negative reciprocity, and 45% with trust. In unreported regressions where we control for each cultural dimension separately, we still find all of them insignificant with the exception of positive reciprocity with a reported positive coefficient but statistically significant only at the 10% level. This result and the higher correlation between altruism and positive reciprocity are due to the similarity between these two concepts. However, the latter dimension measures respondents' propensity to act in a positively reciprocal manner. First, respondents are presented a choice scenario in which they are asked to imagine that they got lost in an unfamiliar area and that a stranger – when asked for directions – offers to take them to their destination. Respondents are then asked which out of six presents (worth between 5 and 30

ROA, firm size, and R&D expenses are insignificant in the specifications with firm fixed effects but have a significant positive impact when we use industry fixed effects. CEO tenure and institutional ownership are insignificant in the specifications with firm fixed effects but have a significant negative impact when we use industry fixed effects. Harjoto, Jo and Kim (2017) show a concave relation between institutional ownership and CSR. Oikonomou, Yin and Zhao (2020) distinguish investors between long term and short term and find the effect to be opposite across these groups and strongly negative for short-term investors. The institutional ownership measure we used taken from Refinitiv is ‘undifferentiated’ as it includes shares owned by any type of ‘institution’, such as mutual funds, hedge funds, banks, pension funds, which are likely to vary in terms of investment horizons. Oikonomou et al. (2020) estimate 44% of the institutional investors to be short term vs. 20% long term. Thus, it is plausible that the majority of investors included in our institutional ownership measure is short-term oriented and the joint effect of institutional ownership on CSR is negative.

Leverage is not significant in the specifications with industry fixed effects, while it has a positive and statistically significant coefficient in the specifications with firm fixed effects. This finding of a positive sign for leverage in our CSR panel regression aligns with results presented in Cronqvist and Yu (2017) and McCarthy et al. (2017). Better CSR performance is generally associated with lower cost of debt (Goss and Roberts, 2011) and therefore with firms preferring debt financing. Sharfman and Fernando (2008) show that firms with better environmental risk management are also those that shift more from equity to debt financing to exploit higher tax benefits associated with their increased debt. Finally, we show that firms led by female CEOs and with a larger amount of free cash flow perform better in CSR as evidenced by the higher scores. The coefficients on these two regressors are positive and strongly statistically significant across all specifications.

Next, we use a firm’s CSR strengths and CSR concerns, separately, as our dependent variables to understand what kind of impact altruism has on different dimensions of a firm’s CSR performance. This disaggregation of the CSR scores is in line with the CSR literature that shows that CSR strength (responsible actions) and CSR concerns (irresponsible actions) are distinct concepts and affect firm characteristics differently (e.g., Kotchen and Moon, 2012; Oikonomou, Brooks and Pavelin, 2012). In

euros, or the respective country-specific equivalents) they would give to the stranger as a “thank you”. Second, respondents are asked to provide a self-assessment about how willing they are to return a favor on an 11-point Likert scale. These two items receive roughly equal weights. The difference with altruism is clearly that altruism does not require the precedent of any action or good deed that one feels it needs to be rewarded or reciprocated, it is a purer selfless action motivated by a focus on others.

Table 3 we report in a succinct manner the results from the same baseline panel regressions as in Table 2 (columns 1 and 3) but using first the overall CSR strength score and then the overall CSR concern score as dependent variables. We find that altruism increases firms' CSR strengths but has no impact on CSR concerns, i.e. corporate socially irresponsible actions. In other words, CEO innate altruism helps to stir the firm towards taking 'good', socially-responsible actions, rather than refraining from 'bad', irresponsible ones. Studies on social capital suggests that CSR strengths rather than concerns create trust and cooperation between the firm and its stakeholders (Guiso et al. 2004; Scrivens and Smith, 2013). Furthermore, it can be argued that CEOs have greater discretionary power and ease to take pro-active actions to generate positive CSR outcomes than to prevent the firm from negative ones. As Servaes and Tamayo (2013) point out, it is very unlikely that a firm with a poor environmental performance has made some 'effort' to obtain such a record. Altruism, being in line with commitment, plays a more important role in improving CSR strengths rather than reducing CSR concerns.

4.3 Robustness checks

Table 4 presents the results of a battery of robustness checks we have performed on the results of the baseline panel regressions discussed in section 4.2. For brevity, for each additional test/regression performed here we report only the specification with firm fixed effects and omit the one with industry fixed effects, as all main results remain unchanged across the two specifications.

First, we adjust the sample to show that the results do not depend on potential selection biases. In column (1) we drop the United Kingdom as the CEO's country of origin from our sample as this is the most dominant country (with 46.17% CEO-observations, see Table A2 in Appendix for details); in column (2) we drop instead those countries that in aggregate represent only 1% of the CEOs' countries of origin in our sample and therefore are less dominant and can represent outliers;¹⁴ in column (3) we exclude from the sample the foreign-national CEOs that were likely born abroad (representing 3 % of the sample) to avoid confounding effects coming from their possible direct experience and connection with the country of origin. As shown in Table 4, in all these checks the main result of a positive impact of CEO altruism on the CSR score survives.

Second, to ameliorate possible concerns of endogeneity coming from the use of contemporaneous dependent and independent variables, in column (4) we lag all independent variables by 1 year while requiring the CEO to be the same one in the prior year to ensure that we

¹⁴The countries are Canada, Finland, Croatia, Ukraine, Japan, Jordan, Lithuania, Brazil, Egypt, and Estonia.

observe the characteristics of the CEO in place at the time when the CSR score is being measured.¹⁵ The results are unchanged.

Third, we add controls for CEO's risk perception and monetary incentives, using measures of sensitivity of CEO's equity-based compensation, i.e., the (natural logs) of the CEO's compensation delta and vega. While the latter (sensitivity to stock volatility) is not statistically significant, the former (sensitivity to stock returns) has a negative impact on CSR performance (as in Fabrizi et al., 2014), but it is significant only at the 10% level. These controls do neither eliminate nor reduce the positive impact of CEO innate altruism on the firm's CSR score.

Fourth, to validate our cultural dimension, in columns (6) and (7) we use alternative measures for our altruism score. In column (6), we use the country-weighted average altruism score discussed in section 3.1. In column (7), we use Schwartz's egalitarianism score as an alternative cultural dimension, related to altruism. Egalitarian cultures seek to induce people to recognize one another as moral equals who share basic interests as human beings. These cultures try to influence their members to internalize a commitment to cooperate and to feel concern for everyone's welfare. People in egalitarian cultures are expected to act for the benefit of others as a matter of choice (Schwartz, 2006). Hence, the definition of Schwartz's egalitarian score closely aligns with our measure of altruism. We observe that these alternative measures of altruism have a significant positive impact on the CSR score of the firm.

The CEO is subject to multiple cultural influences besides the one coming from his/her ancestral country of origin. For example, CEOs' choices can be influenced by the predominant culture of the U.S. County/State where they live. Therefore, in columns (8) and (9) of Table 4 we add a control for the 'local' culture by using: i) a dummy variable named 'Blue State' which is equal to one when the State is governed by Democrats and zero otherwise; and ii) a measurement of U.S county-level social capital. The Blue State dummy can only change every four years (as an outcome of the general elections). It has been used in previous CSR-related studies (e.g., Bae et al., 2021). In particular, Di Giuli and Kostovetsky (2014) observe that firms score higher on CSR when they have Democratic rather than Republican founders, CEOs, and directors, and when they are headquartered in Democratic rather than Republican-leaning states. Following Rupasingha and Goetz (2006) and Jha and Cox (2015), we also use the county-level index of social capital which is based on county 'norms' (census mail response rate and total number of votes cast in presidential elections) and 'networks'

¹⁵ In this way, we exclude observations where the CEO tenure is less than one year, as such CEOs would have little influence on a firm's strategic decisions.

(number of associations and non-profit organizations per 10,000 people). We linearly interpolate the data on social capital which are freely available online for the years 1990, 1997, 2005, 2009, and 2014.¹⁶ Jha and Cox (2015) show that a firm from a high social-capital county exhibits a higher CSR score. In columns (8) and (9) of Table 4 we observe that the estimated coefficients on the variable CEO altruism remain positive and highly significant. Taken together, these checks suggest that CEOs with higher innate altruism rooted in the culture of their country of origin increase firms' CSR scores and that this result survives controlling for the influence coming from the CEOs' local culture within the U.S.

Finally, in unreported checks, we control for the popular Hofstede cultural dimensions (Hofstede, 1980): power distance, individualism, masculinity, uncertainty avoidance, long-term orientation, and indulgence. Our result on altruism is robust to controls for this alternative set of cultural dimensions, suggesting that it is not driven by other cultural traits of the culture of origin.

4.4 Endogeneity controls

A common concern in the literature that investigates the impact of CEO characteristics on firm-specific policies and performance is that the 'match' between the CEO and the firm is endogenous and that this can lead to biased results. In our case, it is possible that a more altruistic CEO might favour those firms that are already more socially-committed and have higher CSR scores.

The first approach we use to address the endogeneity issue is a propensity score matching (PSM) analysis (Rosenbaum and Rubin, 1983) to examine causal treatment effects. We conduct the PSM to account for the possibility that the choice of an altruistic CEO may not be random, but to some extent related to the firm's and/or the CEO's other observable characteristics.

First, we perform a probit regression to estimate a firm's propensity (likelihood) to have an altruistic CEO as a function of firm and CEO characteristics. The dependent variable is a dummy variable that equals one if the CEO has an altruism score above zero, and zero otherwise. In this way, we estimate the probability that the firm will hire a CEO with high innate altruism. Next, we match firms with high-altruistic CEOs (treated firms) with firms with low-altruistic CEOs based on the estimated propensity scores. We use a one-to-one nearest neighbour matching methodology with replacement because it results in higher-quality matches and larger sample size than matching without replacement (Shipman et al., 2017). Then we re-run the regression of equation (1) using the matched sample and the same sets of control variables as in our baseline models in Table 2.

¹⁶ The data have been retrieved from the website: <https://aese.psu.edu/nercrd/community/social-capital-resources> (last accessed on 30 July 2022).

Table 5 shows the results of the PSM. Panel A reports the diagnostic tests that ensure no sample selection bias: after matching the treated and control groups appear balanced and comparable. Panel B shows a very similar distribution for the propensity score for treated and control groups, respectively. Panel C reports the results of the PSM regression. The results remain robust in the matched sample, confirming that the positive impact of CEOs' innate altruism on CSR is not driven by the selected observable characteristics.¹⁷

The second approach we use to address the endogeneity concern is a difference-in-difference research design based on CEO turnover events. This test helps to further establish a causal effect of CEO altruism on CSR performance and to confirm our identification strategy. In particular, we look at CEO turnovers when the predecessor CEO is replaced for plausibly exogenous reasons. We follow Eisfeldt and Kuhnen (2013) and focus only on CEO turnovers due to CEO death, illness, and voluntary retirement. We do not use forced CEO turnovers or unclassified CEO turnovers because these events could be associated to the firm performance and CSR score, hence could be endogenous. We map turnovers identified from CEO changes in ExecuComp to the CEO dismissal database developed by Gentry et al. (2021) and retrieve the reasons for CEO departures for S&P 1500 firms.¹⁸ Event years (year 0) are identified as those years when the predecessor CEO is in his/her last year in office according to the ExecuComp CEOANN flag.

We identify a set of 'treated' turnovers, defined as those turnovers in which a CEO is replaced by a successor CEO from a country of origin that has a higher altruism score. The control group instead includes turnovers in which a CEO is replaced by a successor CEO from a country of origin that has a lower altruism score. Therefore, in our research setting, both treated and control groups have experienced CEO turnover. The difference between the two groups is based on the altruism score of the successor CEO. Consequently, our identified treatment effect can be attributed directly to the altruism score change rather than to the CEO turnover per se. We exclude CEOs with a tenure lower than two years as they may not have enough time to affect firm CSR performance. We are able to identify 334 turnover events in our sample, of which 175 are treated events and 159 are control events.

¹⁷ In unreported results we also perform PSM without replacement and still observe that the CEO innate altruism continues having a positive and significant coefficient.

¹⁸ Gentry et al. (2021) collect news articles and SEC filings for each CEO turnover event and identify eight departure reasons. Then, they use 23 independent coders to read through the articles and categorize each turnover event into one of the eight categories. The data have been retrieved from the website: <https://doi.org/10.5281/zenodo.4543893> (last accessed on 24 November 2022).

We use a difference-in-differences (DiD) approach to analyse the changes in CSR score around these exogenous CEO turnovers in the treated group relative to the control group. Based on this research design, our DiD model is estimated as following:

$$CSR\ Score_{it} = \alpha_1 + \beta Treated_{it} \times CEO\ Turnover_{it} + \gamma Controls_{it} + Year\ FE + Event\ FE + \varepsilon_{it} \quad (2)$$

‘Treated’ is a dummy variable that equals one (both in pre- and post-turnover periods) if the firm has experienced a CEO transition from a less to a more altruistic CEO at some point, and zero for the control firms. ‘CEO Turnover’ is a dummy variable taking the value of one in periods following an exogenous turnover and zero during the pre-turnover period. The difference-in-differences coefficient for ‘Treated × CEO Turnover’ captures the differential effects. A causal effect of altruistic CEOs on corporate social performance would manifest in a positive coefficient on the interaction term since an exogenous change from a less altruistic CEO to a more altruistic CEO should cause an increase in CSR performance. We report the results of the regressions in Table 6.

In column (1) of Table 6, we find that the interaction term Treated × CEO Turnover is positive and statistically significant at the 1% significance level. This provides support for our hypothesis that CEOs with higher innate altruism invest more in CSR activities. In other words, the innate personal preference of a CEO derived from his or her cultural heritage is a determinant of firm level CSR engagement.

In column (2) of Table 6, we perform a similar regression as in column (1), but we add a set of year dummies to verify a parallel trend assumption (the event year, year 0, is omitted and serves as the reference for comparison). The pre-turnover year dummies are all insignificant, suggesting there is virtually no difference between the treated and the control group prior to the turnover. The post-turnover year dummies echo our finding in column (1), that firms’ CSR performance improves after a CEO is being replaced by a more altruistic CEO. Overall, the difference-in-differences tests confirm that firms with a more altruistic replacement CEO tend to have higher CSR ratings after the turnover than firms where the CEO’s altruism score declines after the turnover.

5. The ‘agency conflict’ view versus the ‘good governance’ view of CSR

While we have established a positive relation between CEOs’ innate altruism and firms’ CSR performance in the previous sections, it is not yet clear whether more altruistic CEOs increase CSR investments to the benefit of their shareholders, or whether the positive altruism-CSR link rather represents a mis-use of corporate resources for the personal satisfaction of the CEO. This question

links back to the broader debate in the corporate finance literature on whether CSR is the result of good corporate governance, where firm managers incorporate their stakeholders' interests, or whether CSR is the result of an agency conflict between managers and shareholders at the expense of shareholder wealth (see Ferrell et al., 2016, for a more in-depth discussion of this literature).

In our context, a more altruistic CEO might undertake corporate initiatives and policies that improve the firm's relationship with its stakeholders and/or the appeal of its products and services for shareholders' long-term benefits instead of engaging in self-serving, short-term actions to increase his/her own reward at the expense of shareholders (and stakeholders). In this regard, the positive altruism-CSR link can be viewed as the result of good corporate governance, and we would expect that CEO altruism does not negatively impact shareholders' financial returns.

On the other hand, the increased CSR performance of altruistic CEOs may only serve CEOs' personal motives to align their personal values with their corporate policies, irrespective of whether these CSR investments are financially beneficial to the firm or might even be value destroying. For instance, past literature finds that CEOs can create a favorable public image for themselves and elevate their social status in the corporate community by engaging in CSR (Hayward, Rindova, and Pollock, 2004). Moreover, non-monetary incentives, such as career advancement, reputation, and power can have a positive effect on CSR decisions (Fabrizi et al., 2014). In this agency view of CSR, we would expect that the positive CEO altruism-CSR relation is linked to a worse corporate governance environment in the firm and that CEO altruism negatively affects shareholder returns.

To test the good governance vs. agency conflict views of CSR, we conduct a set of additional tests. First, we explore whether the CEO altruism-CSR link is moderated by the corporate governance environment of the firm. To do so, we divide our sample into sub-samples based on i) firm's corporate governance rating as measured by the E-index and the G-index; ii) level of CEO power,¹⁹ measured by two dummy variables, 'CEO duality' (equal to one if the CEO is also the chairman of the board and zero otherwise), and 'CEO pay slice' (equal to 1 if the percentage of CEO compensation to the total of the five highest-paid managers is above median and 0 otherwise); and iii) the availability of free cash flow, as a CEO disposing of more free cash would have more leeway and resources to decide how to use the firm's funds for personal motives.

¹⁹ Existing literature finds that more powerful CEOs fail to experience discipline from the full range of corporate governance and control mechanisms (Berger et al., 1997) and that a CSR-oriented strategy can be used by the CEO as entrenchment mechanisms to counterbalance the impact of internal corporate control mechanisms (Surroca and Tribó, 2008).

Table 7 shows the results of the sub-sample analysis based on corporate governance. In line with the good governance view of CSR, we observe that the impact of CEO innate altruism on CSR *increases* when corporate governance is at the highest level: the impact of innate altruism on CSR is in fact significant only for those firms with the lowest level of E- and G-indexes, that indicate the highest level of corporate governance. Furthermore, we see that altruism is more effective on CSR when the CEO is less powerful. Specifically, we report that altruistic CEOs significantly improve corporate CSR performance when he/she is not in a dual CEO/Chairman role. The positive effect of CEO innate altruism is more pronounced when the CEO pay is relatively low compared to other executives. Taken together, this set of results provides counter-evidence for the agency view of CSR and suggests that the positive relation between CEO altruism and CSR performance reflects firms' good corporate governance structures. Finally, we find that CEO altruism is more significant for CSR in firms with more free cash flow. While on the one side using free cash flow for CSR may be considered a signal of agency issues (a CEO would use free cash for CSR when this is not part of the regular budgeting and so not considered strategically crucial), on the other side it is also possible that an altruistic CEO can do better CSR if the firm has extra resources to commit to it. This latter explanation could be the reason for the positive impact of free cash flow on the CSR scores which we observe in our baseline regression (Table 2) and would not entail an agency problem.

In our second set of tests, we analyse the link between CEO altruism and firm financial performance. In particular, we look at the impact of CEO altruism on firm's returns and abnormal returns (calculated using the market model, the CAPM model, the Fama-French model, and the Fama-French model with momentum). Our findings reported in Table 8 show that firms with a more altruistic CEO record significantly higher returns (and abnormal returns) during the crisis period of 2008-2009 and the two NBER-classified recession periods (2001, and 2007 – 2009). Instead, altruism does not have any impact on firm's returns over the full-time sample, in the non-crisis years, and in expansionary periods. In other words, CEO altruism does not seem to hurt companies in normal periods, but it does help companies during crisis periods by shielding value for the shareholders. Again, these findings support the good governance view and are in contrast to the agency conflict view. Altruistic CEOs may take a longer-term perspective in managing the firm and thereby may engage in strategic decisions that require more time to come to fruition in terms of higher firm profit. For instance, Haynes et al. (2015) find that self-interest keeps managers focused on the firm's short-term goals, while altruism helps the firm to build and maintain strong human and social capital, which might be particularly valuable in times of crises. Lins, Servaes, and Tamayo (2017) suggest that increased

social capital resulting from CSR activities matters predominantly in periods when trust in corporations at large has eroded, and that during normal times any benefits of social capital are already imbedded in a firm's share price.

5. Conclusions

This study presents first-hand evidence of the positive impact that CEO innate altruism (transmitted from the ancestral culture of origin) has on the CSR performance of the firm the CEO leads. The impact of CEO altruism on CSR is higher when firms have better governance and less dominant CEOs, suggesting that it is not a manifestation of agency conflicts between CEOs and shareholders. Instead, our results support the good governance view of CSR. Further, CEO altruism appears not to have a negative impact on firms' returns and instead protects shareholder returns in times of deep crisis and recessions.

Our finding on the relationship between CEO innate altruism and firm CSR performance survives controls for unobservable firm and industry characteristics and common trends (captured by fixed effects), a large battery of control variables and robustness checks, and further controls for endogeneity, using propensity score matching and a quasi-natural experiment based on changes in CEO altruism following exogenous CEO turnover events.

The results of this study enriches an emerging literature that points at the importance of CEO cultural traits for firms' decision-making and strategies and has an important implication for firm's top management choices, as it shows that CEOs who value altruism more because of their cultural heritage (and above the influence of their local U.S.-county culture) appear more inclined to take corporate socially responsible actions as a result of their higher concern for 'others' (stakeholders, community, future generations).

Table 2. Baseline Panel Regression Results (Overall KLD CSR Score with 5 Categories)

This table shows the results of the baseline panel regressions where the overall KLD CSR score with five categories (KLD_CSR5) is regressed on the altruism score of the CEO's country of origin, several other cultural dimensions scores, firms, and CEO characteristics. Variables' definitions are provided in Appendix. Robust t-statistics are reported in parentheses; they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Dependent Variables:	(1) KLD_CSR5	(2) KLD_CSR5	(3) KLD_CSR5	(4) KLD_CSR5

Table 3. Baseline Panel Regression Results (Overall KLD CSR ‘Strengths’ and ‘Concerns’ Scores with 5 Categories)

This table shows the results of the baseline panel regressions in Table 2 columns (1) and (3) where the overall KLD CSR score with five categories is replaced by the separate scores for ‘strengths’ and ‘concerns’, and these variables are regressed on the altruism score of the CEO’s country of origin, and firms’ and CEOs’ characteristics. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Dependent Variables	(1) KLD_STR5	(2) KLD_STR5	(3) KLD_CON5	(4) KLD_CON5
CEO_altruism	0.208*** (3.060)	0.177*** (3.426)	-0.015 (-0.446)	-0.016 (-0.457)
Firms Characteristics	Yes	Yes	Yes	Yes

Industry FE	No	Yes	No	Yes
Observations	7,823	7,823	7,823	7,823
R-squared	0.272	0.475	0.282	0.290

Table 4. Robustness Checks

The table presents the results of several robustness checks on: firms and CEOs sample selection (columns 1 to 3), use of lagged regressors (column 4), control for CEO compensation-sensitivity variables (column 5); alternative measures of altruism (columns 6 and 7), and control for local culture (columns 8 and 9). All variables are defined in Table A1 of the Appendix. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

	Excluding UK origin	Removing less-dominant origins	Excluding Foreign CEOs	Regressors lagged by one year	Adding CEO compensation-sensitivity	Weighted average of altruism	Schwartz egalitarianism	Blue States	State social capital

Table 5. Propensity Score Matching

Panel A presents the results of the t-tests conducted on the differences between the sample means for all main variables used in the panel regression in the treated and control groups; Panel B illustrates the distribution of the estimated propensity scores for treatment and control firms; Panel C shows the results of the probit model (column 1) and the panel regressions using the matched sample (columns 2 and 3). The probit regression estimates the firm's propensity (likelihood) to have an altruistic CEO as a function of firm and CEO characteristics. The dependent variable is a dummy variable that equals one if the CEO has an altruism score above zero and zero otherwise. Firms with high-altruism CEOs (treated firms) are matched with firms with low-altruism CEOs based on the estimated propensity scores from the probit model. We use a one-on-one nearest neighbourhood matching methodology with replacement. The baseline panel regression is estimated using the matched sample and the same sets of control variables as in our baseline models in Table 2. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Table 6. CEO Turnover Events

This table reports in column (1) the results of a panel regression where the KLD CRS score is regressed on the interaction variable $Treated \times CEO_Turnover$ where 'Treated' is a dummy variable equal to 1 if the event is part of the 'treated group', i.e. for those turnover events where the new CEO comes from a country of origin with a higher altruism score than the previous CEO (otherwise the dummy is 0); and 'CEO_Turnover' is a dummy equal to 1 after a quasi-natural turnover event occurs due to CEO death, illness and voluntary retirement for both treated and control groups. For the treated group, the interaction variable is zero before (including) the event year and one after the event year; for the untreated group, it is zero throughout all the years. The event year is the last year that the old CEO is in his/her position (the last year that he/she has the CEO annual flag in ExecuComp). In column (2) a parallel trends test is performed, and the event year (year 0) is the reference for comparison. Before5+ indicates a dummy variable that is equal to one in all years before year -5 and zero otherwise; Before4 is one in year -4 and zero otherwise; etc. Post5+ indicates a dummy variable that is equal to one in all years after year 5 and zero otherwise; Post4 is one in year 4 and zero otherwise; etc. CEO must have at least a tenure of two consecutive years to be included in the sample. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Table 7. Sub-sample tests on agency channel

The table presents a sub-sample analysis of the impact of CEO altruism on CSR to uncover a possible agency channel. Panels A and B show the results of the multivariate panel regressions on sub-samples of firms at different quartiles of the E-index and G-index distributions (a higher quartile indicates worse corporate governance); Panel C on sub-samples of firms at different quartiles of the distribution of free-cash flow; Panel D on sub-samples based on CEO duality (a dummy equal to 1 if the CEO is also the Chairman of the board); Panel E on sub-samples based on CEO pay slice (a dummy equal to 1 if the percentage of CEO compensation to the total of the compensation of the five highest paid executive is above median and zero otherwise). Columns 1 to 4 presents the panel regressions with year and industry fixed effects; Columns 5 to 8 with year and firm fixed effects. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Table 8. Effect of CEO Altruism on firms' performance

This table presents the results of panel regressions of CEO innate altruism on firm's monthly raw returns and abnormal returns calculated using the market model, the CAPM model, the Fama-French model, and the Fama-French model with momentum, controlling for all firms' and CEOs' characteristics used in our baseline panel regressions in Table 2, plus four factors' loadings for the asset pricing models used. Panel A shows the results for the full sample; Panel B for the global financial crisis period of 2008-2009; Panel C for all years excluding the global financial crisis years of 2008 – 2009; Panel D focuses on the two NBER-classified recession periods (2001, and 2007 – 2009); Panel E on the rest of the sample, i.e., expansionary periods. Robust t-statistics are reported in parentheses, and they are calculated from estimated standard errors clustered at the firm level. ***, **, and * represents respectively statistical significance at the 1%, 5%, and 10% level.

Appendix

Table A1. Variable Descriptions

Variable Name	Description	Source
CSR Measures		
KLD_CSR5	The sum of adjusted Community, Diversity, Employee, Environment and Human rights corporate social responsibility scores. Adjusted CSR is calculated by scaling the raw strength and concern scores of each category by the number of items of the strength and concern of that category in the year and then taking the net difference between adjusted strength and concern scores for that category.	MSCI KLD
KLD_STR5	The sum of adjusted Community, Diversity, Employee, Environment and Human rights CSR strength scores. The adjusted strength score is calculated by scaling the raw strength of each category by the number of items of the strength category in the year.	MSCI KLD
KLD_CON5	The sum of adjusted Community, Diversity, Employee, Environment and Human rights CSR concern scores. The adjusted concern score is calculated by scaling the raw concern of each category by the number of items of the concern category in the year.	MSCI KLD
COM	Net adjusted CSR score (strength less weakness) for the Community	MSCI KLD
DIV	Net adjusted CSR score (strength less weakness) for the Diversity	MSCI KLD
EMP	Net adjusted CSR score (strength less weakness) for the Employee	MSCI KLD
ENV	Net adjusted CSR score (strength less weakness) for the Environment	MSCI KLD
HUM	Net adjusted CSR score (strength less weakness) for the Human rights	MSCI KLD
Cultural Dimensions		
CEO_altruism	A measure of willingness to donate to the charity. Measured as a combination of one qualitative and one quantitative item. The qualitative question asked respondents how willing they would be to give to good causes without expecting anything in return on an 11-point scale. The quantitative scenario depicted a situation in which the respondent unexpectedly received 1,000 euros and asked	Global preference survey

	them to state how much of this amount they would donate.	
CEO_altruismmean	Weighted average of altruism score, where the weight is determined by the frequency appeared in passengers' records across origins associated with a CEO's last name.	Global preference survey
CEO_patience	A measure of patience, i.e. how individuals prefer the earlier payment to the larger delayed payment.	Global preference survey
CEO_risktaking	A measure of how individuals trade off risky payments and sure payments.	Global preference survey
CEO_posrecip	A measure of the individuals' willingness to reciprocate positively.	Global preference survey
CEO_negrecip	A measure of the individuals' willingness to reciprocate negatively.	Global preference survey
CEO_trust	A measure of willingness to trust strangers.	Global preference survey
CEO_egalitarianism	A measure of egalitarian culture. Egalitarian cultures seek to induce people to recognize one another as moral equals who share basic interests as human beings. They try to socialize their members to internalize a commitment to cooperate and to feel concern for everyone's welfare. People are expected to act for the benefit of others as a matter of choice.	Schwartz (2006)

Firm and CEO Characteristics

ROA	Return on asset, Earnings before interest and taxes (EBIT)/Total assets (AT)	Compustat
Leverage	Total debt, (DLTT + DLC)/Total assets (AT)	Compustat
Firm Size	Firm size, Log of total assets (AT) of a firm.	Compustat
Log Free Cash-Flow	Log of free cash flow, Cash flow from operations (OANCF) less capital expenditures (CAPX)	Compustat
R&D	R&D intensity, Annual firm dollars spent on R&D (XRD) scaled by total assets (AT)	Compustat
Inst_Ownership	Total institutional ownership	Refinitiv
Log CEO Age	Log of CEO age	ExecuComp
CEO Gender	CEO gender	ExecuComp
Log CEO Tenure	Log of CEO tenure in month	ExecuComp

Log CEOComp Delta	Log of CEO compensation Delta. Delta is defined as the dollar change in an executive's wealth for a 1% change in stock price.	ExecuComp
Log CEOComp Vega	Log of CEO compensation Vega. Vega is defined as the dollar change in an executive's wealth for a 1% change in volatility.	ExecuComp
Corporate Governance and Additional Control Variables		
G-index	G-Index is the sum of binary variables based on the number of shareholder rights-decreasing provisions a firm has. The index ranges from a feasible low of 0 to a high of 24; a high score is associated with weak shareholder rights.	ISS
E-index	E-index is the sum of binary variables of the six most important entrenchment provisions as described in Bebchuk, Cohen and Ferrell (2009).	ISS
CEO duality	A dummy variable that is equal to one if the CEO is also the Chairman and zero otherwise.	BoardEx
CEO payslice	CEO pay slice is defined as the fraction of the aggregate compensation of the firm's top-five executive team captured by the CEO, as defined in Bebchuk, Cremers and Peyer (2011).	ExecuComp
Social capital	The social capital of the county where the firm is headquartered constructed as in Rupasingha, Goetz and Freshwater (2006) A higher number indicates greater social capital.	Rupasingha, Goetz and Freshwater (2006)
Blue state dummy	A dummy variable that is equal to one if Democratic wins in the gubernatorial elections and zero otherwise. The dummy variable changes every four years except in New Hampshire and Vermont where governors only serve two-year terms.	CQ Press U.S. Political Stats
