Abstract

This paper analyzes the determinants of bank acquisitions both within and across countries in the EU-25 over the period 1997-2004. The findings of this paper are broadly in line with those of the academic literature on the subject and which are mainly based on the US experience. Although theory suggests that performance may be less important in determining European targets than U.S. targets, our results suggest poorly managed EU-25 banks (high cost to income and low profitability) are more likely to be acquired by other EU-25 banks both in the same country and across countries. Nevertheless, this underperformance of target banks does not hold for listed banks. The probability of being acquired is larger for banks that are quoted in the stock market which is consistent with the disciplinary character of listing in the stock markets. Finally, antitrust concerns make less likely acquisitions by banks operating in more concentrated markets within the same country.

Keywords: bank acquisitions, merger gains, probability of acquisition.
JEL Codes: G21, G34.

1- Introduction

The development of a single financial market has been a long time objective for the European Union (EU). Its achievement received further impetus with the single market for financial services in the early 90's and later by the introduction of the Euro.¹ Pan-European banks could, in theory, have developed long ago, in practice cross-border banking remained rather limited until the launching of the Euro. Also, in theory, it is possible for large cross-border banks to expand their activities via the opening of *de novo* operations. However, practice around the world has shown that *de novo* operations are usually a costly and slow way for a bank to enter a new market.² Thus, if a single financial market is to develop through cross-border banking, most likely it will require the acquisition of banks across Member boundaries within the EU.

While the EU has seen significant overall consolidation in its financial sector according to the European Commission (2005), the Economics and Finance Ministers of the EU expressed dissatisfaction with the extent of cross-border consolidation in 2004.³ In response to a request from the Ministers, the European Commission (2005) studied the extent of cross-border takeovers and found that it was proceeding more slowly in the financial sector due to regulatory and economic barriers to takeovers.

An important regulatory barrier was political interference and misuse of supervisory powers. Perhaps partially due to these barriers, domestic deals are significantly larger than cross-border deals leading to "domestic champions" (European Commission, 2005).

Another important economic barrier according to the European Commission (2005) was the limited opportunities to pay for the deal by reducing costs. One important reason why costs were difficult to cut is that cross-border deals typically involved few duplicative operations (or "***non-overlapping fixed costs***" (emphasis in original)). Cost cutting opportunities were also limited by governmental restrictions on laying off employees.

The barriers to cross-border deals may not only reduce the frequency of cross-border takeovers but also change the types of banks that are acquired relative both to the type of banks acquired in domestic EU deals and relative to a market with fewer regulatory constraints such as the United States (US). For example, the cost inefficiency of potential takeover targets may be less important in cross-border deals in the EU than in domestic EU and US transactions.

¹ This importance arises both as a part of the goal of developing a single market for all goods and services and to facilitate the implementation of a common monetary policy throughout the Euro area.

² Dermine (2003) indicates that the number of foreign bank subsidiaries in Europe is high relative to the number of foreign branches. Both foreign subsidiaries and branches are more the result of takeovers than of greenfield investments. Also, Cabral et al. (2002) point out that the most effective way of gaining access to the retail banking sector is to merge with or acquire an existing local bank.

³ See the Annex to the European Commission (2005) for a summary of the results of the Minister's 13 September, 2004 discussion.

The purpose of this paper is to identify the differences between the banks that were targets versus those that were not acquired in the first 25 members of the EU (the EU-25) over the period from 1997 through 2004. The results are compared with prior studies of takeovers in the US and the EU. The sample also includes both in-country and cross-border takeovers, allowing some comparison of the relative importance of improving operations and other considerations in domestic versus cross-border takeovers.

The rest of the paper is organized as follows. Section 2 presents the recent experience of domestic and cross border bank acquisitions in the EU. The economic rationale of bank acquisitions both domestic and cross border as presented in the academic literature is analyzed in section 3. Section 4 describes the data as well as the univariate analysis while section 5 presents the results of the discrete choice models for our sample of European banks. Finally, section six concludes.

2- The recent experience of domestic and cross border bank acquisitions in the EU

In the EU, the consolidation of the banking system is reflected in the overall increase of the size of the international banking groups and the importance of their cross border presence. Over the last decade, banks in the EU responded to the structural changes in the financial sector and increased competition by consolidating their activities in order to increase in size and scope. Against this background, the number of credit institutions in the EU-25 fell from 9,747 in 2001 to 8,684 in 2005.⁴ This decrease was to a large extent explained by the M&A within national boundaries. Allen et al. (2005) report 438 transactions that involved at least one credit institution of which 68 per cent involved within border transactions over the period 2001-2004.⁵ M&A activity and, consequently, the downward trend in the number of credit institutions has significantly increased the level of concentration in the local banking markets. On average (asset weighted average), the five largest institutions held 33 percent of total bank assets in the EU-25 in 1997 and this increased to 45 per cent in 2004.⁶

The cross border bank consolidation that has occurred to date has not gotten to the point where it is likely to lead to real pan-European institutions in the short term. While the average acquiring banks are larger in cross-border deals than domestic deals according to the European Commission (2005), the average targets are the same size in domestic deals

⁴ See the European Central Bank (2006). Credit institutions are banks, savings banks and savings and loan undertakings (cooperative banks). The number of credit institutions in each Member State includes the credit institutions under the law of that country, regardless of whether or not they are subsidiaries of foreign banks, and the branches of foreign banks in that Member State. If a foreign bank has several branches in a given country, then they are counted as a single branch. However, if the same bank has several subsidiaries, the latter are counted separately because they are considered to be separate legal entities.

⁵ See Díaz, García, and Sanfilippo (2004) for an analysis post-merger performance of European banks that looks at both the acquirers of banks and of other financial institutions.

⁶ See the European Central Bank (2006). These figures for the EU-25 are computed as the weighted average of the C5 concentration ratios for each individual countries, using total assets of each national banking system as weights. The set of five largest credit institutions in each country may vary over time.

as in cross-border deals. The acquirer is more likely to take a minority ownership position in cross-border deals than in domestic deals.⁷ Moreover, until very recently cross-border banking consolidation has mainly taken place within regional areas in the EU. Indeed, two linkages can be clearly distinguished in the Benelux, the Nordic countries and the new member states of the EU from central and Eastern Europe. In particular, in the latter case intra-regional deals represent 90% of the total value of the deals within EU15 involving at least one Nordic entity. This ratio is around 60% for the Benelux region.

Acquisitions in the new member states occurred perhaps because many central and eastern European countries suffered banking crises in the early years of their independence and allowed their failed banks to be acquired by foreign banks.⁸ Other special circumstances have fostered those acquisitions such as run-up to EU membership and the privatization process. Three new member states joined Luxembourg (the EU-15 country with the most cross-border banking) in having over 80 percent of their banking assets in banks from other EU countries, while three other new member countries have almost 60 percent. Four of the new members also rank relatively highly with regard to the percentage of assets from third countries.⁹ Consequently, the accession of the new members has given added impetus to cross-border banking issues in the EU (Garcia, 2007).

The literature on takeovers in the EU reflects the growing interest in financial consolidation in the EU. However, the literature on the EU remains small relative to the large number of studies of US bank takeovers. No study has yet examined the determinants of takeovers across the entire EU25, albeit a few studies discussed in the following section have examined the determinants of takeover targets in part of the EU.

Some related studies have analyze the expected economic outcome of takeovers is to analyze the stock market returns of the participants around the time of the takeover announcement. Cybo-Ottone and Murgia (2000) study a sample of acquisitions announced in European markets where at least one of the parties was a bank from 1988 through 1997. As is often found in event studies of takeover announcements, the targets has significantly positive abnormal returns and the acquirer has insignificant abnormal returns, findings which held for both domestic and cross-border takeovers. However, the weighted average returns of the combined firms are significantly positive for domestic deals and insignificant for cross-border deals. In contrast, Beitel, Schiereck, and Wahrenburg (2004) look at acquisitions in the EU 15 where the acquiring organization was a bank over the sample period from 1985 to 2000. They find that the weighted average returns of the acquirer and target are not significantly influenced by whether the

⁷ Minority shareholdings are shareholding that are not controlling stakes and, by definition below 50%.

⁸ See Lanine and Vander Venet (2007) for a test of the efficiency versus market power hypotheses as explanations of bank takeovers in central and Eastern Europe.

⁹ Data are lacking for a number of individual new member states because the ECB does not publish data when the number of subsidiaries or branches is less than three.

takeover is a cross-border acquisition in a multiple regression framework with controls for several possible determinants of the weighted average returns.¹⁰

3- Determinants of bank acquisitions: A review of the literature

Most of the literature on the characteristics of targets in bank takeovers focuses on U.S. banks. The U.S. study most closely related to our paper is by Hannan and Pilloff (2006). They note that most U.S. studies either focus on narrow subsets of banks, such as publicly traded banks, or they have problems identifying changes in control.¹¹ Hannan and Pilloff (2006) start with the universe of U.S. banks but avoid errors in identifying changes in control by using a commercial merger data set from SNL Financial which focuses exclusively on takeovers where there was a change in control.¹² Hannan and Pilloff (2006) separate their sample into in-market and out-of-market acquisitions, a split that roughly corresponds to our split between domestic and cross-border deals.

A few recent papers also examine the determinants of takeovers in Europe. Molyneux (2003) highlights the desire to avoid regulatory, information and other barriers as the main motive for overseas expansion. Moreover, analyzing a sample of M&As that took place in Europe between 1995 and 2000, he also finds that domestic deals are more motivated by cost efficiency considerations, whereas earnings diversification may be more important for cross-border bank deals. Lanine and Vander Vennet (2007) examine the determinants of takeover targets and acquirers in Central and Eastern Europe over the 1995 through 2002 period as a part of a broader study of the implications of bank takeovers in that area. Pasiouras, Tanna and Gaganis (2007) analyze takeover targets and acquirers in the EU-15 over the 1997 to 2002 period with a focus on the role of differences in regulation.¹³

This section surveys the literature on the determinants of bank takeovers, with special attention to the results in Hannan and Pilloff (2006), Lanine and Vander Vennet (2007), and Pasiouras, Tanna and Gaganis (2007). The section is organized around the various factors typically found to be the most likely determinants of bank acquisitions.

¹⁰ Similarly, Campa and Hernando (2006), analyzing a sample of financial firms in the European Union over the period 1998-2002, did not find significant differences in value creation between domestic and cross-border deals.

¹¹ The studies with very large samples, sometimes the universe of U.S. banks, often rely on the merger of bank charters to identify takeovers. Hannan and Pilloff (2006) note that this procedure produces errors in both directions because a large fraction of U.S. banks are owned by bank holding companies (BHCs). Bank mergers may occur without a change in control if a BHC merges two banks in which it previously had a controlling interest. Conversely, a change in control may occur without the target bank losing its charter if the target is acquired by a BHC that maintains the target's charter.

¹² Hannan and Pilloff (2006) note that the vast majority of their takeovers occur in when the acquirer's ownership interest goes from near zero (often exactly zero) to 100 percent. Our use of a 20 percent threshold for change in control reflects a typical pattern of staggered shareholding acquisitions of banks in the EU. The participation of 20 percent is considered a permanent investment.

¹³ See also Buch and DeLong (2003), and Vander Vennet (2003) for related analysis.

3.1 *Target operating performance*

One of the main motives underlying acquisitions is to improve the efficiency of the target. These gains are more likely to be achievable if the target bank is underperforming. Therefore, indicators of performance should contain explanatory power on the likelihood of being acquired. In particular, banks with lower profitability or greater inefficiency might be more attractive for acquisition. However, while it is true that underperforming banks provide greater opportunities for improvement, they are also more risky, especially if the source of the underperformance is lots of bad loans. In such a case, a local acquirer may be in a better position to identify the problems that need to be fixed than an out-of-market acquirer. Thus, indicators of performance should a priori be more relevant to explain in-market acquisitions.

Hannan and Pilloff (2006) find that less profitable banks in the US are more likely to be acquired, regardless of the type of acquirer (intra state or interstate bank), and, in a number of cases, a measure of inefficiency is found to be positively related to the probability of acquisition.¹⁴ The results from the two European studies differ. The coefficients on the expense ratios in equations predicting targets are insignificant in Lanine and Vander Venet (2007); however, the on the coefficient cost to income is significantly positive. In contrast, the coefficient on the return on average equity is significantly negative in Pasiouras, Tanna and Gaganis (2007).

3.2 *Capitalization*

An often researched determinant of the attractiveness of a bank as a potential target is its degree of capitalisation. A number of different explanations for this relationship have been considered in the literature (see Hannan and Pilloff, 2006). On the one hand, there are arguments favouring the positive relationship between banks' capitalization and the likelihood of being a target. First, if acquirers face regulatory pressure to increase capitalisation they may seek highly capitalised targets. Second, if high capitalization indicates the inability of a bank to diversify assets, more capitalized banks would be more attractive for better diversified acquirers. Third, the managers of banks with high capital ratios may be operating further below their profit potential because of reduced pressure to obtain high earnings. On the other hand, some arguments suggest a negative relationship. First, if capitalization is seen as an index of managerial ability or efficiency, then better capitalized banks would be less attractive to potential buyers, since the potential gains from a better management are smaller. Second, if a bank's capitalisation is very low and the bank is near default, an acquisition by a well capitalized and efficient acquirer might be even fostered by the supervisor. Finally, another argument for a negative link

¹⁴ See Amel and Rhoades (1989) and Moore (1997) for additional references supporting the hypothesis that acquisitions serve to transfer assets from poorly managed to better managed firms. By contrast, Hannan and Rhoades (1987) or Hadlock et al. (1999) report evidence against the hypothesis of poor managerial performance as measured by ROA. Hadlock et al. (1999) argue that this evidence is most consistent with an entrenchment hypothesis, where management teams with significant ownership positions block attempts to be acquired at a reasonable price.

suggested by those authors is that buyers prefer high leveraged (poor capitalized) targets because it enables them to maximize the magnitude of post-merger performance gains relative to the cost of achieving those gains. For a given asset size, the purchase price premium of the acquisition is generally lower, the higher capitalized is the bank.

Akhigbe et al. (2004) find a positive relationship between capital and the likelihood of being acquired in their sample of publicly traded banks in the U.S. However, most studies, including Hannan and Pilloff's (2006) results for their entire sample, and Lanine and Vander Vennet (2007) analysis of Central and Eastern European countries none of which were members of the EU before 2004, find that banks with higher capital-asset ratios are less likely to be acquired. The coefficient on the capital to asset ratio is insignificant in Pasiouras, Tanna and Gaganis (2007) using a sample of European countries that have been EU members since 1996 (EU-15).

3.3 *Prospects for future growth*

Banks experiencing high growth may be more attractive targets, as the potential gains arising from improved management after the acquisition are likely to be larger in banks that are operating in expanding markets. Consistent with this hypothesis, some U.S. studies from the 1980s, including Hannan and Rhoades (1987) and Cheng et al. (1989), find that the likelihood of acquisition is positively related to the growth rate of the assets of the target bank. However, Moore (1996) argues that slower growing targets may make more attractive to buyers looking to increase the target's growth rate. Consistent with Moore (1996), Pasiouras, Tanna and Gaganis (2007) obtain a negative coefficient on the past growth rate. Hannan and Pilloff (2006) and Lanine and Vander Vennet (2007) do not include a growth variable.

3.4 *Size*

Smaller banks may be more attractive to acquirers to the extent that these banks are more easily integrated into an acquirer's operations. Smaller banks are also less likely to raise concerns by the competition authorities. On the other hand, if the acquiring organization is seeking economies of scale or market power through the acquisition then acquiring one large bank may provide those economies or market power sooner and possibly at lower cost than a series of small acquisitions.

Hannan and Pilloff (2006) find that larger banks are more likely to be acquired when they estimate their model using their full sample. Lanine and Vander Vennet (2007) and Pasiouras, Tanna and Gaganis (2007) also have a significantly positive coefficient on total assets. However, when Hannan and Pilloff (2006) focus on acquisitions by smaller acquirers they find that larger banks are less likely to be acquired, consistent with the hypothesis that merger post-merger integration becomes more difficult as the size of the target grows relative to that of the acquirer.

3.5 *Industry concentration*

The degree of concentration of the banking industry potentially affects the likelihood of acquisitions by conditioning the impact of the deals on the intensity of market competition and, consequently, affecting the likelihood of a sharp opposition by antitrust authorities. Therefore, the influence of concentration on acquisition likelihoods is likely to differ between domestic and cross-border deals since the reaction of competition authorities to domestic deals will likely to be more severe in more concentrated markets. However, in the case of cross-border deals that are less likely to be challenged by antitrust authorities, concentration may even positively affect the conditional probability of a cross-border acquisition if foreign acquirers are attracted by the higher margins that characterize more concentrated markets. Hannan and Pilloff (2006) fail to find any evidence that competition issues are an important determinant of takeover targets.¹⁵ The coefficient on their measure of market concentration is consistently insignificant and the sign of the coefficient on their measure size does not change between in-market and out-of-market acquisitions. However, Pasiouras, Tanna and Gaganis (2007) report a significantly negative coefficient on the five firm concentration ratio in their sample of European takeovers, perhaps reflecting differences in concentration with Hannan and Pilloff's U.S. sample.

3.6 *Management incentives*

To the extent that managers of the target banks may lose their job positions or, at least, may suffer a reduction in their executive autonomy or in their job responsibilities, they may oppose takeover bids even if the deals are value maximizing for their shareholders. In this line, Hadlock et al. (1999) explored the role of different variables that proxy target management incentives (such as ownership structure, board composition or characteristics of the top executive) in the likelihood of a bank to be acquired.

The results in Hadlock et al. (1999) indicate that banks with higher levels of management ownership are less likely to be acquired, especially in acquisitions where target managers depart from the banking organization following the acquisition. Moreover, the authors do not find that poorly performing banks, as measured by ROA, are particularly likely to be acquired. Thus, they argue that this evidence is most consistent with the entrenchment hypothesis, where management teams with significant ownership positions block attempts to be acquired at a reasonable price, rather than with the discipline hypothesis.

In this paper, we do not explore the role of management incentives due to the lack of appropriate data. Nevertheless, these types of incentives are likely to have more explanatory power in studies on industries where hostile takeovers are more prevalent. However, as Cheng et al. (1989) indicate, this type of deal is rare in banking and difficult to implement due to regulatory hurdles. There are several recent examples in the European banking industry of hostile takeovers that did not succeed.

¹⁵ Hannan and Rhoades (1987) and Moore (1997) find that the effect of concentration on the acquisitions likelihood is significantly positive for out-of-market acquisitions but negative for in-market acquisitions, thus reflecting the deterrence effect of antitrust enforcement.

3.7 Other target characteristics

Lack of appropriate data also precludes us from considering in our empirical study other bank level potential determinants of bank acquisitions that have been studied in the U.S. literature. First, Wheelock and Wilson (2000) consider different indicators of asset quality and find that some proxies for suspect loans are negatively related to the probability of acquisition. Second, Hannan and Pilloff (2006) study the role of the composition of the target's clientele and they find that the higher is the local nature of deposits the higher is the likelihood of being acquired (see also Ahkhigbe et al., 2004). They argue that this result may reflect the possibility of cross-selling new products to newly acquired local depositors. Finally, both Wheelock and Wilson (2000) and Hannan and Pilloff (2006) considers bank's age to capture the effect of length of time since opening in the probability of being acquired. They generally find a negative sign which they interpret as the age variable capturing an unobservable element of bank success.

4. Empirical approach

4.1 Statistical approach

We first attempt to identify those observable characteristics that are related to a bank becoming a target. For this purpose, we estimate a logit model:

$$P_{jt} = \frac{\exp(X_j \beta)}{(1 + \exp(X_j \beta))}$$

where P_{jt} is the probability of bank j being acquired in period t ; X_t is a vector of explanatory characteristics (both bank-specific and market-specific) relevant to acquisitions in period t ; and β is a vector of coefficients.

As a second approach, we estimate a multinomial logit model that allows the effect of the explanatory variables to differ for acquisitions where both the target and the acquirer banks are located in the same country (state) versus acquisitions where the target and acquired banks are located in different countries (states).

$$P_{jt}^D = \frac{\exp(X_j \beta^D)}{(1 + \exp(X_j \beta^D) + \exp(X_j \beta^{CB}))} \quad \text{and} \quad P_{jt}^{CB} = \frac{\exp(X_j \beta^{CB})}{(1 + \exp(X_j \beta^D) + \exp(X_j \beta^{CB}))}$$

where P_{jt}^D and P_{jt}^{CB} denote the probability of being acquired in a domestic or cross-border transaction, respectively; and β^D and β^{CB} are vectors of coefficients. Thus, the

influence of the explanatory characteristics (both bank-specific and market-specific) on the likelihood of being acquired is allowed to differ between acquisitions in the same or in a different country.

4.2 Empirical model

The empirical model is based on models that have been estimated using U.S. data with some modifications to reflect data availability and market differences in Europe. The model for estimating the probability of being acquired by another bank takes the form:

$$P_{jt} = \alpha + \beta_{op} (\text{Operating Performance}_{jt}) + \beta_{cap} (\text{Capitalization}_{jt}) + \beta_{gr} (\text{Growth}_{jt}) + \beta_{mp} (\text{Size / Market Power}_{jt}) + \beta_o (\text{Other}_{jt}) + \beta_t (\text{Time Fixed Effects}) + \varepsilon_{jt}$$

The multinomial models for P_{jt}^D and P_{jt}^{CB} are similar except for the appropriate change in the dependent variable.

Our empirical model has three proxies for the target's operating performance. The first is Bankscope's cost-to-income ratio, with higher values indicating greater cost inefficiency.¹⁶ Thus, the expected sign on the coefficient for this ratio is positive if worse performing banks provide greater opportunities to acquire but it may be negative if their managers are more resistant to being acquired. The other two proxies are the net interest margin which measures the interest spread between what the bank earns on its assets and pays on its liabilities (net interest income as a percentage of earning assets), and the return on average equity which measures of the overall returns to shareholders. The expected coefficients on these variables are negative if worse performing banks are more attractive targets but they may be positive if they are more resistant to being acquired.

The capitalization of the target is measured as the ratio of equity to total assets. As the studies of U.S. takeovers have found, the expected sign depends on which of several effects dominate. On the other hand, the relationship will be positive if: (1) acquirers face supervisory pressure to maintain or raise their post-acquisition capital ratios, (2) targets with higher capital ratios have less diversification or are operating less efficiently. The expected sign will be negative if: (1) higher target capital ratios are associated with more managerial ability, (2) banks that are near or below supervisory minimums are more likely to sell out, or (3) the acquirers will pay higher premiums as a proportion of equity for less well capitalized banks.

Growth opportunities are proxied with the annual growth rate of the target's assets and the annual growth rate of the target country's gross domestic product (GDP). The expected sign on both growth rates is positive if growing targets offer acquirer's the potential of larger gains from improved management. However, the sign may be negative if slower growing targets offer acquirer's better opportunities to improve management.

¹⁶ Bankscope defines this as overhead expense as a percentage of the sum of net interest revenue and other operating income.

The proxy for a bank's size is its total assets at year end. The expected sign on this variable is positive if acquirers primarily value the fact that larger targets provide the acquirer with a larger position in the target's marketplace all else equal. However, the expected sign is negative to the extent that acquirer's primary concern is the difficulty in combining the target's operations with that of the acquirer.

The proxies for local market concentration are the five firm concentration ratio and the Hirschman-Herfindahl index (HHI) where the market is defined as the country in which the bank is headquartered. All else equal, more concentrated markets may offer the acquirer higher profit opportunities. However, higher concentration levels may reduce the probability of being acquired by an in market bank to the extent that local bank supervisors seek to maintain competitive banking markets.

The *Other* variables proxy for the target's willingness to be acquired (including the type of business specialization: commercial banks, medium and long term banks and holding company banks) and for the unique conditions in the new members states of the EU. The proxy for the target's willingness is its stock listing, which takes a value of one if the bank is listed on the stock exchange and zero otherwise. The expected sign on this variable is positive as acquirers may have more ways of pressing reluctant target managers and boards to accept a takeover. That is potential acquirers of banks that are listed may threaten to acquire some of the target's stock and to appeal to the target's other shareholders for support of its takeover bid. The proxy for the new member states takes a value of one if the bank is headquartered in those countries that joined the EU after 2000 and before the last enlargement in 2007. The expected sign on this variable is positive. Acquisitions in the new member states often occurred because many central and eastern European countries suffered banking crises in the early years of their independence and allowed their failed banks to be acquired by foreign banks. Other special circumstances have fostered those acquisitions such as run-up to EU-25 membership and the privatization process.

5. Data and descriptive analysis

5.1 Sample selection

The sample consists of banks from the EU-25 available on the Bankscope database from 1996 (just before the introduction of the euro) through 2004 (the last year prior the adoption of the international financial reporting standards –IFRS– by the EU banks).^{17,18} Our database includes 1342 EU-25 largely private banks of which, 75 are

¹⁷ BankScope is a financial database covering 10,500 World Banks. It offers subscribers data up to 8 years of detailed spreadsheet information, compiled by FITCHIBCA mostly from the balance sheet, income statement and applicable notes found in audited annual reports. It also includes data details on ownership, produced by Bureau Van Dijk, such as lists of shareholders and lists of banking subsidiaries.

¹⁸ The characteristics of the sample banks are as follows for the EU25: Commercial banks; mortgage and real estate banks, medium and long term credit banks, bank holding companies, which all of them report on local GAAP. Banks with shareholders outside of the EU have been eliminated.

independent institutions and the rest are subsidiaries of financial or non financial institutions as of last reporting year.¹⁹

The data on acquisitions were obtained from the M&As Deals Module of Thomson One Banker over the period starting in 1997 and ending just before the the switch from national accounting standards to the IFRS in 2004. We have included only those transactions that involved a change in control where both the target and the acquirer were banking institutions. We have considered that change in control takes place when a bank or bank holding company that owns less than 20% of the target's equity increases its shareholding to at least 20%. This also represents a typical pattern of staggered shareholding acquisitions of banks in the EU (European Commission, 2005) and the minimum threshold for authorization by the prudential supervisors of the host country as established in the EU Directive.²⁰ The sample of acquisitions in the EU-25 contains 157 deals, of which 39 were cross-border.

Table 1 provides information on the geographic distribution of the overall sample and the takeover distribution (by host country of the target). Takeovers are split into domestic takeovers where the acquirer is from the same country and cross-border takeovers. Domestic takeovers are approximately three times as common during our sample period. Table 1 also provides a breakdown of the number of takeovers by year.

5.2 Descriptive analysis of the sample of EU-25 banks

Descriptive statistics and univariate analysis are broken down three ways and are provided in Tables 2, 3, and 4. Table 2 compares the performance of target and non-target banks for the entire sample. Table 3 compares the same performance measures for targets relative to the median values in the bank's market in which operates. Table 3 also compares the performance of listed and non-listed targets. Finally, Table 4 provides a univariate analysis of the differences between targets in domestic takeovers and the targets in cross-border takeovers. The observations included in the target sample correspond to the year immediately before a target bank is acquired whereas those included in the non-target sample correspond to the year immediately before a bank has not been acquired. The variables are defined in the Appendix.

¹⁹ 21 are public or government controlled banks of which 9 are part of the Nordea Group. Only one of these banks belonging to the Nordea Group was a target bank in our sample. This deal cannot be considered a privatization.

²⁰ In almost all cases, once an acquirer has more than 20 percent it ultimately buys at least 50 percent of the target during the study period. In this regard, it should be borne in mind that according to the IFRS adopted by the EU countries, the participation in the shareholding of 20% is considered as a permanent investment.

Target vs non- target banks

The results in Table 2 show that acquired bank in our sample are less profitable and have a higher ratio of cost to income at both the mean and median values.²¹ The median target bank had higher net interest revenue and other operating income as percentages of average assets but the differences are not significant at the mean values. The overall profitability results are consistent with the hypothesis that acquirers seek out poorly performing targets.

The scale of the target banks is generally similar to that of banks that were not acquired in Table 2, regardless of whether scale is measured by total assets, deposits and short-term funding, net income or employees. The only significant differences are in the median value of deposits and other short-term funding, the number of employees, where the target is significantly larger at the median but not at the mean. Finally, target banks are also not significantly different in their leverage ratio.

Target banks vs national markets

Table 3 shows means and medians of the financial ratios of the target banks with respect to the median value of their respective market in which operates. The expense, revenue and profitability results in Table 3 for the sample as a whole are broadly consistent with those in Table 2. Targets have significantly higher cost to income ratios and other operating income to asset ratios (but not significantly different net interest revenue to average asset ratios). The net result is that targets have significantly lower profitability by all three measures (pre-tax operating income to assets, return on average assets and return on average equity). However, when the results are broken down by whether the target is listed on a stock exchange, the statistical significance appears to be entirely driven by banks that are not listed.²² This finding is consistent with Campa and Hernando (2006) who, analyzing a sample of acquisitions involving European listed banks over the period 1998-2002, show that although targets display on average a worse financial performance than their buyers, they do not significantly underperform with respect to the average bank of their national market.

Although the average target bank is similar in scale to the average bank in the EU in Table 2, Table 3 shows that target banks are typically larger along all four dimensions (total assets, deposits and short term funding, net income and total employees) than other banks in their country. The greater scale holds for all four of the scale variables, in terms

²¹ The difference of means tests are generated from regressions that pool the data from the two groups of banks being compared. These regressions are specified as: $X_{it} = a + b \cdot D_{it} + e_{it}$, where X_{it} is the variable being tested, D_{it} is a dummy equal to 1 for banks in the second of the two pooled samples, and e_{it} is a random disturbance term with zero mean. The statistical difference of b from zero provides the test of statistical significance for the difference of means. In turn, the difference of median tests are nonparametric two-sample tests for the null hypothesis that the two samples of banks being compared were drawn from populations with the same median.

²² There are 221 listed banks and 1121 non-listed banks in our EU-25 sample.

of mean. The sole exception is that the mean scale in terms of net income of listed banks is no different from the mean scale of other banks in the target's home country.

Finally, results in terms of capitalization are not conclusive perhaps due to the small number of observations (see Table 3): the mean of the difference of the total capital ratio with respect to the country median is significantly positive while the median of this difference is significantly negative. This suggests that target banks tend to be less capitalized than their country median but there are a few non-listed target banks with very high capital ratios that seem to determine the positive sign of the mean.

Domestic vs cross-border deals

Table 4 shows the comparison between means and medians for both types of target banks and the statistical significance of the differences in their ratios. Differences between domestic and cross-border targets are in almost all cases not statistically significant. The only exceptions are the medians of the other operating income and pre-tax operating income over average asset ratios which are significantly higher in the case of cross-border targets. These results suggest that, a priori, both types of target banks tend to share similar financial characteristics.

6. Multivariate analysis: The probability of being acquired

Determinants of the likelihood of a bank being acquired

The results of estimating the probability of being acquired in any takeover in the EU-25 presented in Table 5 are broadly consistent with the results found in Hannan and Pilloff (2006), and Pasiouras, Tanna and Gaganis (2007) with one exception. Consistent with their results, the coefficient on the cost to income ratio is negative and statistically significant. These results suggest that acquirers prefer to acquire banks with expense cutting opportunities. The coefficients on net interest revenue and return on average equity are insignificant.

The coefficient on the equity to asset ratio is close to zero and is statistically insignificant in Table 5. In contrast, Hannan and Pilloff (2006), and Pasiouras, Tanna and Gaganis (2007) both found a negative coefficient on this variable.

Probably the biggest inconsistency with the results typically obtained from U.S. data relate to growth. Hannan and Pilloff (2006) do not include a growth variable, but other studies that have done so tend to obtain a significantly positive coefficient. The annual total asset growth rate of the target's assets is consistently insignificant in Table 5, but the GDP annual growth rate of the local economy is consistently significantly negative. This result suggests that once we have controlled for bank-specific financial indicators, acquisitions are more likely in cyclical downturns. However, these results are broadly consistent with Pasiouras, Tanna and Gaganis's (2007) finding of a significantly negative coefficient on banks growth.

The results for size, larger banks are more likely to be acquired is consistent with Hannan and Pilloff (2006), Lanine and Vander Venet (2007), and Pasiouras, Tanna and Gaganis (2007). We also use two proxies for market concentration, the five largest banks concentration ratio and the HHI. Differently from Pasiouras, Tanna and Gaganis (2007) but consistently with Hannan and Pilloff (2006), the market concentration variables are not statistically insignificant.

The coefficients on both whether the bank was listed and whether it was headquartered in a New Member State are significant. Banks that are listed in stock exchanges are more likely to be acquired, even after having controlled for size.²³ Significantly positive coefficients are obtained for the dummy for New Member States reflecting the fact that bank acquisitions have been relatively frequent in these countries during the study period.

Determinants of the likelihood of a bank being acquired by a domestic or foreign EU bank

Tables 6 displays the results of the estimation of a multinomial logit model that allows for different effects of the explanatory variables on the likelihood of being acquired by banks in the same country and on the likelihood of being acquired by banks in a different country within the EU.²⁴ Overall, the pattern of the results for the explanatory variables related to the conditional probability of domestic acquisitions is similar to those reported in the previous paragraphs. However, there is one important difference: the concentration variables are both negative and statistically significant indicating that antitrust concerns make acquisitions by banks operating in the same country less likely in more concentrated markets. Interestingly, the coefficients of the concentration variables are positive and statistically significant in explaining cross border acquisitions within the EU. Cross-border deals are less likely to increase concentration and, thus, raise competition concerns because a cross-border acquirer is likely to have little or no market share in the target's domestic market. Additionally, foreign banks may be attracted by the monopoly rents which might be obtained in more concentrated markets, without these deals being challenged by antitrust authorities.

Most of the variables explaining the probability of a cross-border takeover are statistically insignificant, including the cost to income ratio. In addition to the significant positive coefficients on the concentration measures, the other significant coefficient is on stock exchange listing. These coefficients are positive suggesting that listed banks are more likely to be acquired.

Table 7 displays the estimation of multinomial logit models where the bank-specific financial ratios have been replaced for the corresponding ratios defined with respect to median ratio of the banks operating in the same country. The biggest differences with

²³ As a robustness check, we also estimated the model including a variable that takes a value of 1 if the bank is independent, that is not owned by another firm (we use the Bankscope criteria for independence). This variable is not significant and the results are qualitatively similar to those reported in the text.

²⁴ Multinomial Model: 1= Domestic target, 2= Cross border target, 0= Non target

Table 6 are that the coefficient on the cost to income ratio becomes significantly positive and the coefficient on stock market listing becomes statistically insignificant. Banks which are being acquired are less efficient than other banks in their country but are no more likely to be listed on a stock exchange.

7. Conclusions

In spite of the high interest on the determinants of bank acquisitions, there is a relative dearth of empirical studies based on European banks' data. This paper attempts to fill this gap by identifying the determinants of bank acquisitions both within countries and across countries in the EU-25. To this end, we use a sample of 1342 banks that contains 157 deals, of which 39 were cross-border. These deals were announced between 1996 and 2004. The results on the determinants of cross-border transactions should be taken with some caution given the limited number of deals.

The findings of this paper are broadly in line with those of the academic literature on the subject including Hannan and Pilloff (2006), Lanine and Vander Vennet (2007), and Pasiouras, Tanna and Gaganis (2007). More precisely, the major conclusions of this paper are as follows:

- Although theory suggests that performance may be less important in determining European targets than U.S. targets, our results suggest poorly managed EU-25 banks (high cost to income and low profitability) are more likely to be acquired by other EU-25 banks both in the same country and across countries (although in the latter case only if compared to the median of thea respective market). This result supports the hypothesis that efficiency gains are more likely to be achievable if the target bank is underperforming. As a matter of fact, targets are less efficient and less profitable than the median of its national market. Nevertheless, this underperformance of target banks does not hold for listed banks.
- Larger banks are more likely to be acquired by other banks in the same country. Moreover, targets are larger than the median of the market. This finding seems to reflect that the acquisition of large banks is more beneficial in terms of achieving product diversification and penetration in new market segments. This may also suggest that the supervisory authorities like to create national champions in the banking industry.
- Domestic acquisitions have been more likely in the New Member States.
- One area where domestic and cross-border takeovers appear to differ is in the area of concentration. Domestic takeovers are less likely in more concentrated markets but cross-border takeovers are more likely. This seems to indicate that outside banks within the EU are attracted by monopoly rents, which might be obtained in more concentrated markets, without these deals being challenged by antitrust authorities.

In further work that should soon be completed, we also plan on comparing the statistical significance of the difference between the coefficients on domestic takeovers with those for cross-border takeovers. We will then be able to say more about the differences between domestic and cross-border takeovers within the EU-25.

Annex:²⁵**CAPITAL ADEQUACY RATIO**

This ratio is the total capital adequacy ratio under the Basle rules. It measures Tier 1 + Tier 2 capital which includes subordinated debt, hybrid capital, loan loss reserves and the valuation reserves as a percentage of risk weighted assets and off balance sheet risks. This ratio should be at least 8%. This ratio cannot be calculated simply by looking at the balance sheet of a bank but has to be calculated internally by the bank. At their option they may publish this number in their annual report.

EQUITY / TOT ASSETS

As equity is a cushion against asset malfunction, this ratio measures the amount of protection afforded to the bank by the equity they invested in it. The higher this figure the more protection there is.

RETURN ON AVG ASSETS (ROAA)

This is perhaps the most important single ratio in comparing the efficiency and operational performance of banks as it looks at the returns generated from the assets financed by the bank.

The mention "AVG" means that the item is averaged using the arithmetic mean of the value at the end of year t and t-1. In order not to lose information, when figures are available for one year only, ratios implying average figures are nevertheless calculated using the values of the only available year.

RETURN ON AVG EQUITY (ROAE)

The return on equity is a measure of the return on shareholder funds. Obviously here the higher the figure the better but one should be careful in putting too much weight on this ratio as it may be at the expense of an over leveraged balance sheet. The mention "AVG" means that the item is averaged using the arithmetic mean of the value at the end of year t and t-1. In order not to lose information, when figures are available for one year only, ratios implying average figures are nevertheless calculated using the values of the only available year.

COST TO INCOME RATIO

This is one of the most focused on ratios currently and measures the overheads or costs of running the bank, the major element of which is normally salaries, as percentage of income generated before provisions. It is a measure of efficiency although if the lending margins in a particular country are very high then the ratio will improve as a result. It can be distorted by high net income from associates or volatile trading income.

NET INTEREST MARGIN

This ratio is the net interest income expressed as a percentage of earning assets. The higher this figure the cheaper the funding or the higher the margin the bank is commanding. Higher margins and profitability are desirable as long as the asset quality is being maintained.

²⁵ Source BankScope.

NET INT INC / AVG ASSETS

This ratio indicated the same but expressed as a percentage of the total balance sheet.

OTH OP INC / AVG ASSETS

When compared to the above ratio, this indicates to what extent fees and other income represent a greater percentage of earnings of the bank. As long as this is not volatile trading income it can be seen as a lower risk form of income. The higher this figure is the better.

NON INT EXP / AVG ASSETS

Non interest expenses or overheads plus provisions give a measure of the cost side of the banks performance relative to the assets invested.

PRE-TAX OP INC / AVG ASSETS

This is a measure of the operating performance of the bank before tax and unusual items. This is a good measure of profitability unaffected by one off non trading activities.

The variables Relative Cost to Income Ratio %, Relative ROAE %, Relative Net Interest Margin, and Relative Equity / Total Assets % are defined as the individual bank ratio minus the median ratio of banks operating in that country.
